Measurement of CP Violation in $B_s \rightarrow J/\Psi\Phi$ Decay at CDF

Gavril Giurgiu (for the CDF Collaboration)
Johns Hopkins University

Fermilab Wine and Cheese Seminar
June 11, 2010

Introduction

- *CP* violation means that the laws of nature are not invariant under the simultaneous transformation of Charge and Parity

- Charge conjugation transforms particles into anti-particles

- Parity transformation is a mirror reflection (space inversion)

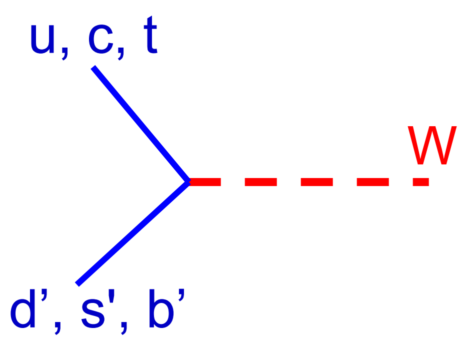
- Parity conservation was first questioned by T.D. Lee and C.N. Yang in 1956 when they argued that there was no experimental evidence for parity conservation in weak interactions

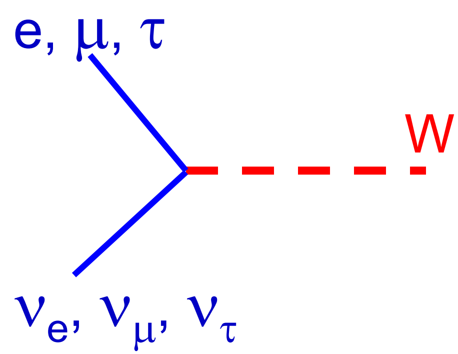
- Same year, C.S. Wu showed that Parity is violated in beta decays of Cobalt nuclei

- The combined *CP* was soon adopted as the correct symmetry, just to be shown wrong by Cronin and Fitch in 1964 when they showed that *CP* is violated in neutral Kaon decays

CP Violation in the Standard Model

- *CP* violation enters the Standard Model through complex phases in mixing matrices that connect up-type fermions with down-type fermions via W bosons:





$$\begin{pmatrix} d' \\ s' \\ b' \end{pmatrix} = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix} \begin{pmatrix} d \\ s \\ b \end{pmatrix}$$

- Cabibbo-Kobayashi-Maskawa (CKM) quark mixing matrix transforms quark mass eigenstates into weak eigenstates and induces *CP* violation in the hadronic sector

- Pontecorvo-Maki-Nakagawa-Sakata (PMNS) neutrino mixing matrix
  → induces neutrino oscillations and possibly *CP* violation in lepton sector

$$\begin{bmatrix} U_{e1} & U_{e2} & U_{e3} \\ U_{\mu1} & U_{\mu2} & U_{\mu3} \\ U_{\tau1} & U_{\tau2} & U_{\tau3} \end{bmatrix}$$

CKM Matrix

- Expand CKM matrix in $\lambda = V_{us} = \sin(\theta_{Cabibbo}) \approx 0.23$

$$\begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix} \approx \begin{pmatrix} 1-\frac{1}{2}\lambda^2-\frac{1}{8}\lambda^4 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda+\frac{1}{2}A^2\lambda^5[1-2(\rho+i\eta)] & 1-\frac{1}{2}\lambda^2-\frac{1}{8}\lambda^4(1+4A^2) & A\lambda^2 \\ A\lambda^3[1-(1-\frac{1}{2}\lambda^2)(\rho+i\eta)] & -A\lambda^2+\frac{1}{2}A\lambda^4[1-2(\rho+i\eta)] & 1-\frac{1}{2}A^2\lambda^4 \end{pmatrix}$$

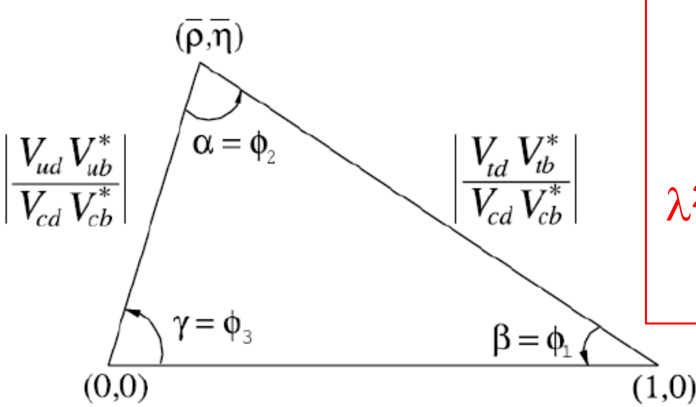
- To conserve probability CKM matrix must be unitary
  → Unitary relations can be represented as "unitarity triangles"

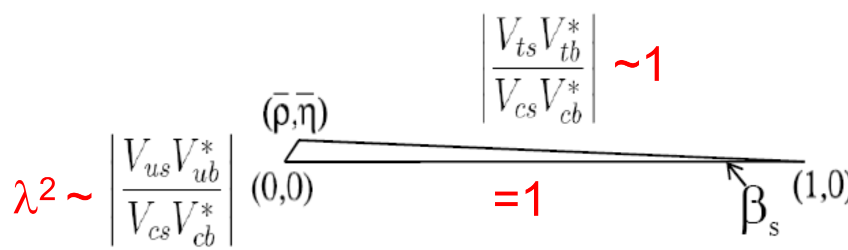
unitarity relations:

$$V_{ud}V_{ub}^* + V_{cd}V_{cb}^* + V_{td}V_{tb}^* = 0$$

$$V_{us}V_{ub}^* + V_{cs}V_{cb}^* + V_{ts}V_{tb}^* = 0$$

unitarity triangles:



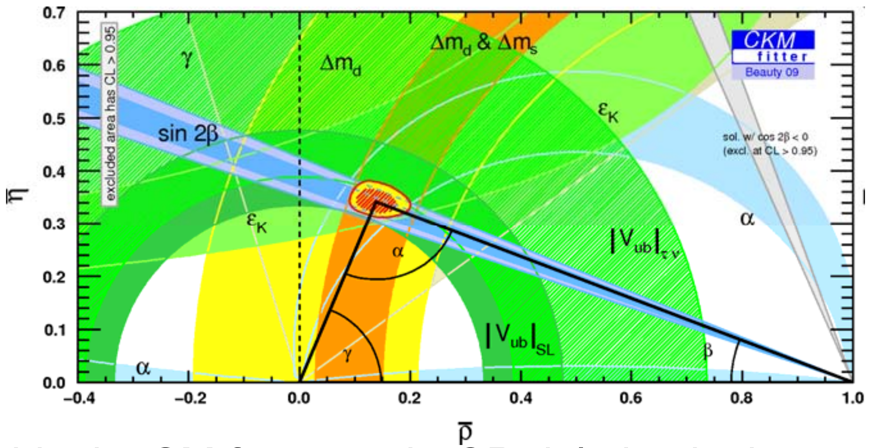


Small *CP* violation phase β_s accessible in $B_s \rightarrow J/\psi\Phi$ decays

Why Look for CPV in B_s System ?

- *CP* violation has been studied in various Kaon and *B*-meson decays

- CKM matrix is well constrained by experimental data



- Within the SM framework, *CP* violation in the quark sector is too small to explain the matter - antimatter asymmetry in the universe

- Could still find large *CP* violation within the SM in the lepton sector
  - initial asymmetry between leptons and anti-leptons may induce baryon asymmetry through baryon number violation processes (lepto-genesis)
  - long baseline neutrino experiments will investigate CP violation in neutrino sector

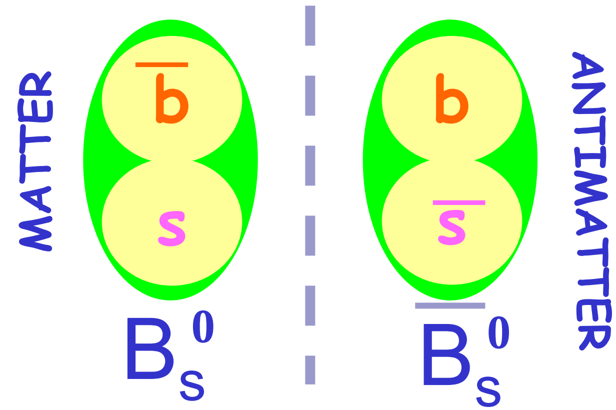
- Alternatively we look for sources of *CP* violation beyond the SM in the quark sector

- Promising place to look for non-SM *CP* violation is the neutral B_s meson system

Neutral B_s System

- Time evolution of B_s flavor eigenstates described by Schrodinger equation:

$$i\frac{d}{dt}\begin{pmatrix}|B_s^0(t)\rangle \\ |\bar{B}_s^0(t)\rangle\end{pmatrix} = \left(\mathbf{M} - \frac{i}{2}\Gamma\right)\begin{pmatrix}|B_s^0(t)\rangle \\ |\bar{B}_s^0(t)\rangle\end{pmatrix}$$



-Diagonalize mass (M) and decay (Γ) matrices
→ mass eigenstates :

$$|B_s^H\rangle = p\,|B_s^0\rangle - q\,|\bar{B}_s^0\rangle \qquad |B_s^L\rangle = p\,|B_s^0\rangle + q\,|\bar{B}_s^0\rangle$$

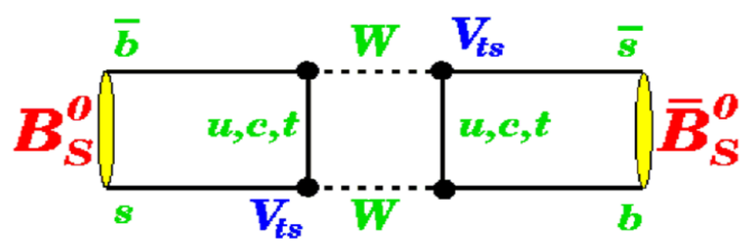
- Flavor eigenstates differ from mass eigenstates and mass eigenvalues are also different:

$\Delta m_s = m_H - m_L \approx 2|M_{12}|$

→ B_s oscillates with frequency Δm_s
precisely measured by

CDF $\Delta m_s = 17.77 \pm 0.12\ ps^{-1}$

DØ $\Delta m_s = 18.56 \pm 0.87\ ps^{-1}$



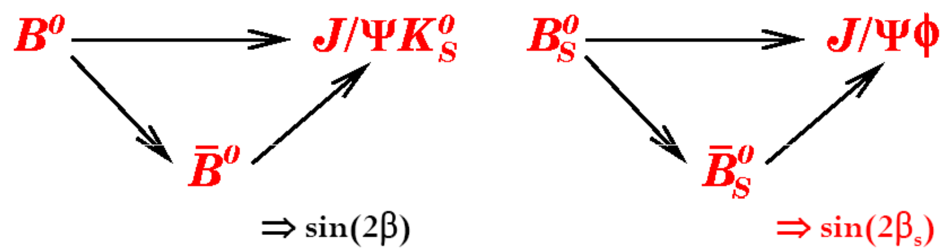
- Mass eigenstates have different decay widths

$\Delta\Gamma = \Gamma_L - \Gamma_H \approx 2|\Gamma_{12}| \cos(\Phi_s)$ where $\phi_s^{SM} = \arg\left(-\frac{M_{12}}{\Gamma_{12}}\right) \approx 4 \times 10^{-3}$

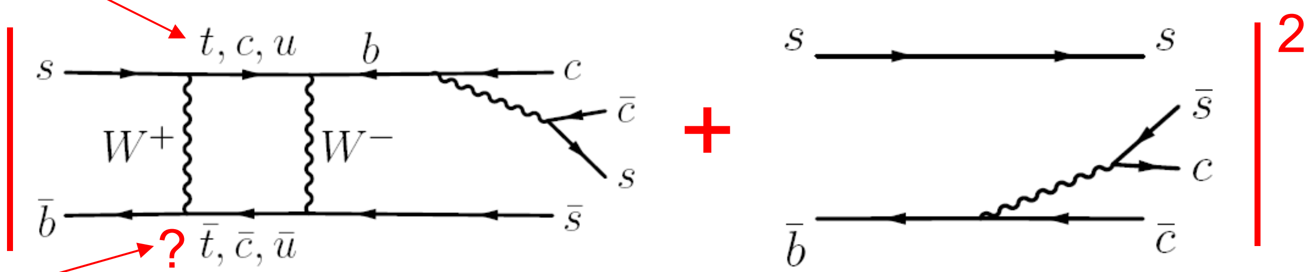
CP Violation in $B_s \to J/\Psi\Phi$ Decays

- Analogously to the neutral B^0 system, *CP* violation in B_s system is accessible through interference of decays with and without mixing:

dominant contribution from top quark



Decay rate ~



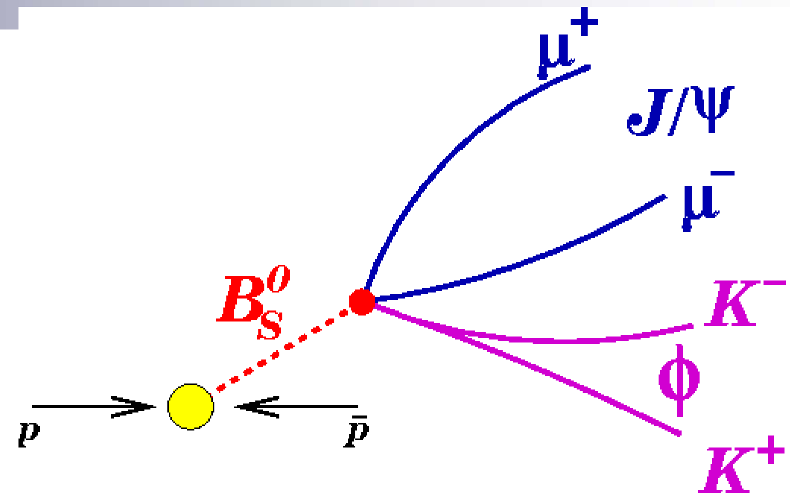
New Physics particles ?

$$\beta_s^{SM} = \arg(-V_{ts}V_{tb}^*/V_{cs}V_{cb}^*) \approx 0.02$$

$$\begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix}$$

- *CP* violation phase β_s in SM is predicted to be very small, $O(\lambda^2)$
- New physics particles running in the mixing diagram may enhance β_s
    - large β_s → clear indication of New Physics !

$B_s \rightarrow J/\Psi\Phi$ Decays

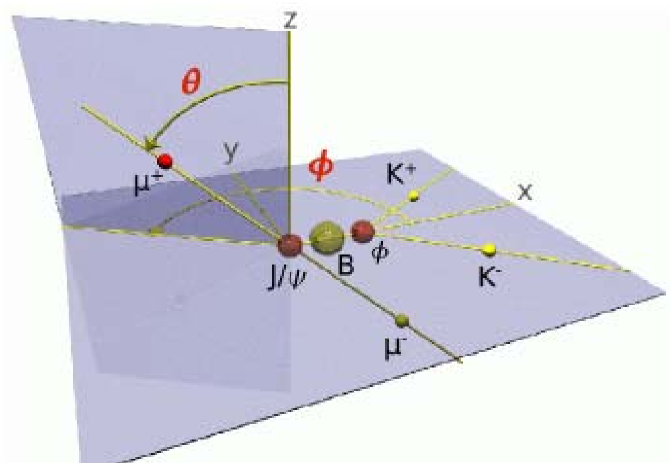


- Measure:
  - B_s lifetime τ_s
  - B_{sH}, B_{sL} decay width difference $\Delta\Gamma_s$
  - *CP* violating phase β_s

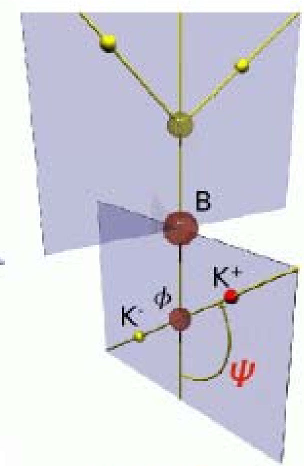
- Decay of B_s (spin 0) to J/Ψ (spin 1) and Φ (spin 1) leads to three different angular momentum final states:

$L = 0$ (s-wave), 2 (d-wave) → *CP even* (= short lived or light B_s if no *CPV*)

$L = 1$ (p-wave) → *CP odd* (= long lived or heavy B_s if no *CPV*)



J/ψ rest frame



φ rest frame

- Three decay angles $\vec{\rho} = (\theta, \phi, \psi)$ describe directions of final decay products $\mu^+ \mu^- K^+ K^-$

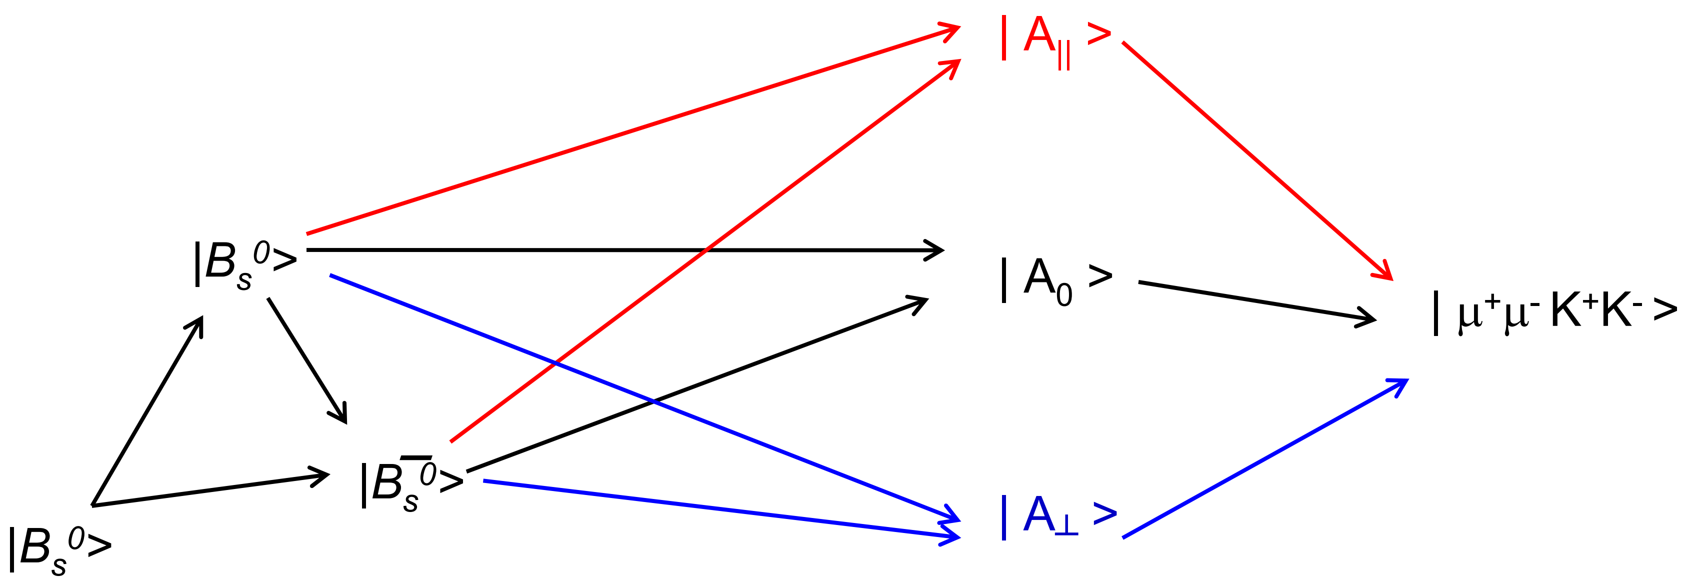
Transversity Basis

- Use "transversity basis" in which the vector meson polarizations w.r.t. direction of motion are either (Phys. Lett. B 369, 144 (1996), 184 hep-ph/9511363):

- transverse (⊥ perpendicular to each other) → *CP odd*

- transverse (∥ parallel to each other) → *CP even*
- longitudinal (0) → *CP even*

- Corresponding decay amplitudes: A_0, $A_\parallel$, $A_\perp$



Decay Rate

- $B_s \rightarrow J/\Psi\Phi$ decay rate as function of time, decay angles and initial B_s flavor:

$$\frac{d^4P(t,\vec{\rho})}{dtd\vec{\rho}} \propto |A_0|^2\mathcal{T}_+ f_1(\vec{\rho}) + |A_\parallel|^2\mathcal{T}_+ f_2(\vec{\rho}) + |A_\perp|^2\mathcal{T}_- f_3(\vec{\rho}) + |A_\parallel||A_\perp|\mathcal{U}_+ f_4(\vec{\rho}) + |A_0||A_\parallel|\cos(\delta_\parallel)\mathcal{T}_+ f_5(\vec{\rho}) + |A_0||A_\perp|\mathcal{V}_+ f_6(\vec{\rho}),$$

time dependence terms

angular dependence terms

terms with β_s dependence

$$\mathcal{T}_\pm = e^{-\Gamma t} \times [\cosh(\Delta\Gamma t/2) \mp \cos(2\beta_s)\sinh(\Delta\Gamma t/2) \mp \eta\sin(2\beta_s)\sin(\Delta m_s t)],$$

terms with Δm_s dependence present if initial state of B meson (B vs anti-B) is determined (flavor tagged)

$$\mathcal{U}_\pm = \pm e^{-\Gamma t} \times [\sin(\delta_\perp - \delta_\parallel)\cos(\Delta m_s t) - \cos(\delta_\perp - \delta_\parallel)\cos(2\beta_s)\sin(\Delta m_s t) \pm \cos(\delta_\perp - \delta_\parallel)\sin(2\beta_s)\sinh(\Delta\Gamma t/2)]$$

$$\mathcal{V}_\pm = \pm e^{-\Gamma t} \times [\sin(\delta_\perp)\cos(\Delta m_s t) - \cos(\delta_\perp)\cos(2\beta_s)\sin(\Delta m_s t) \pm \cos(\delta_\perp)\sin(2\beta_s)\sinh(\Delta\Gamma t/2)].$$

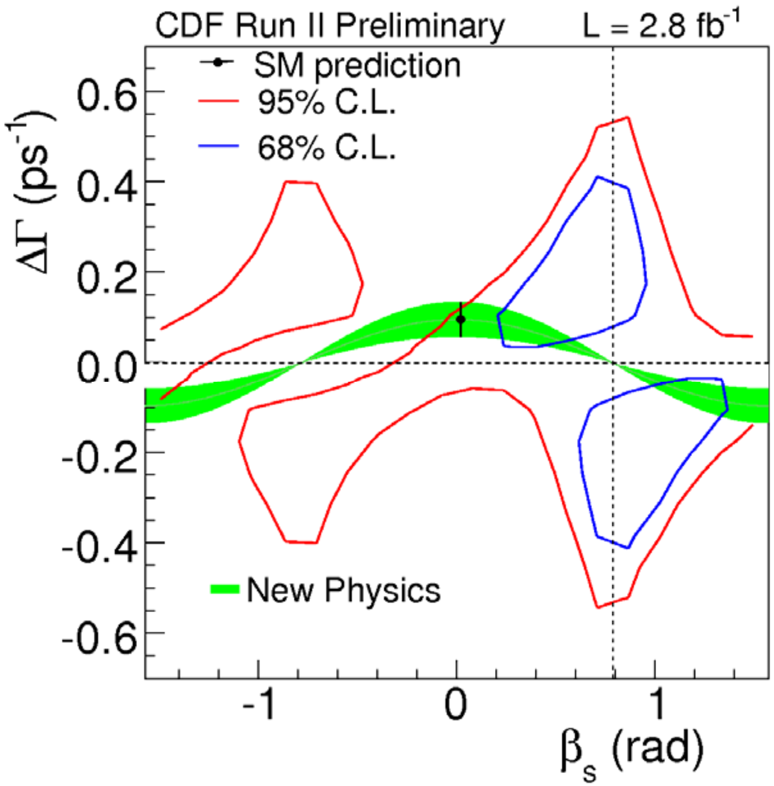
'strong' phases:

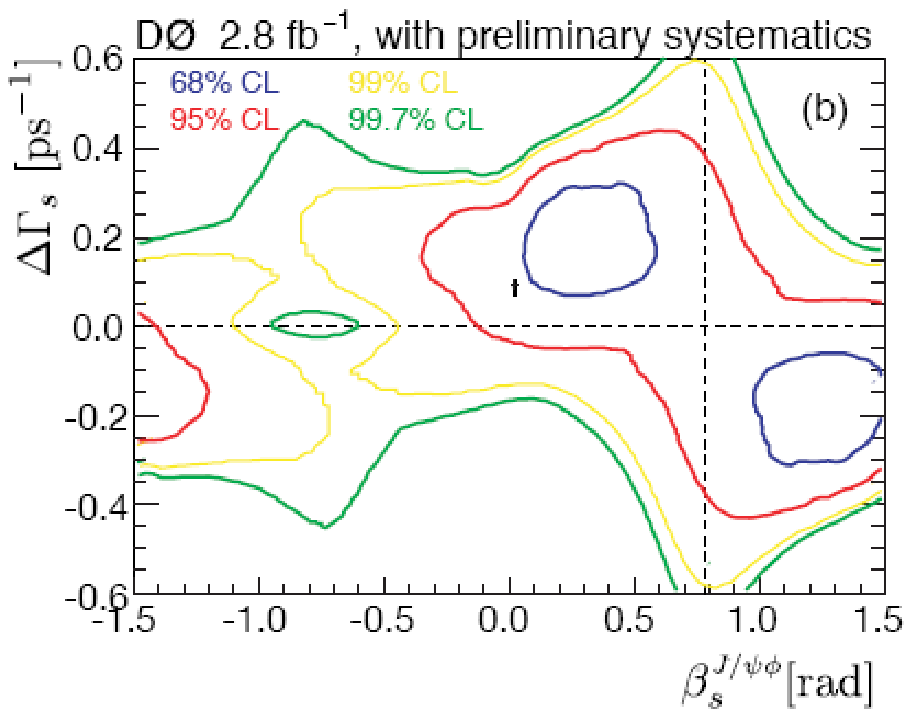
$$\delta_\parallel \equiv \mathrm{Arg}(A_\parallel(0)A_0^*(0))$$
$$\delta_\perp \equiv \mathrm{Arg}(A_\perp(0)A_0^*(0))$$

- Identification of *B* flavor at production (flavor tagging) → better sensitivity to β_s

Status Before This Update

- Both CDF (public note 9458) and DØ (conference Note 5933-CONF) showed ~1.5σ deviations from SM in the same direction

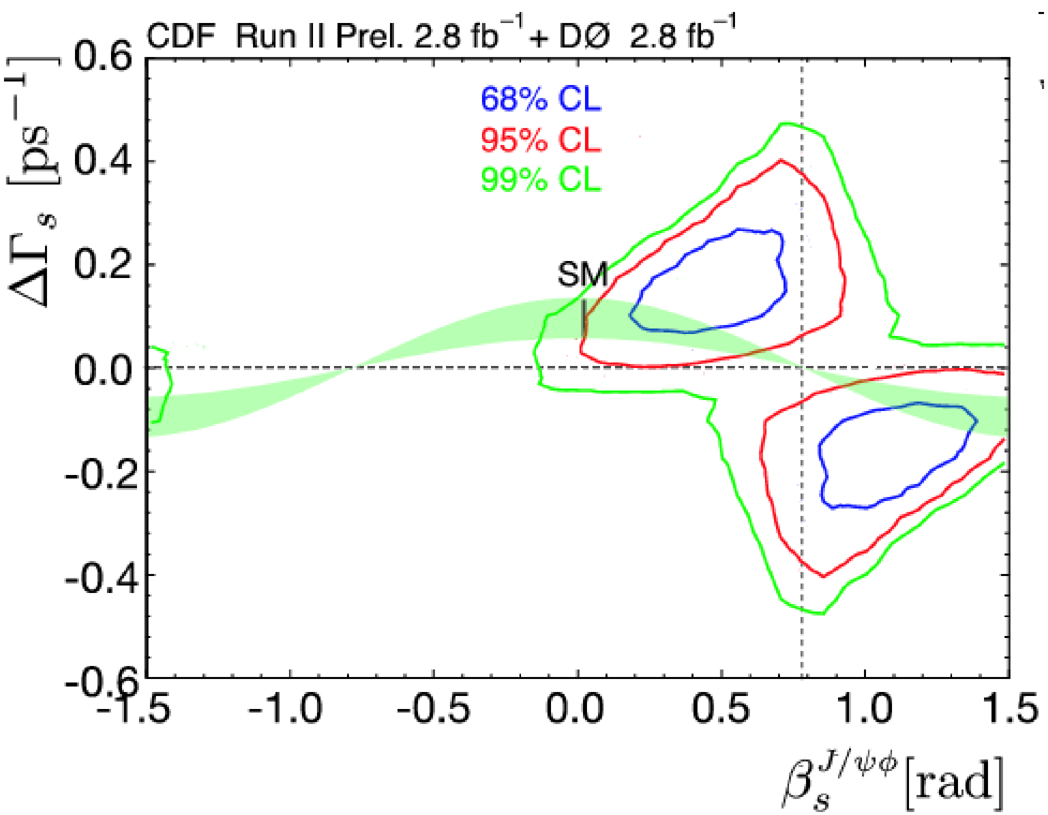


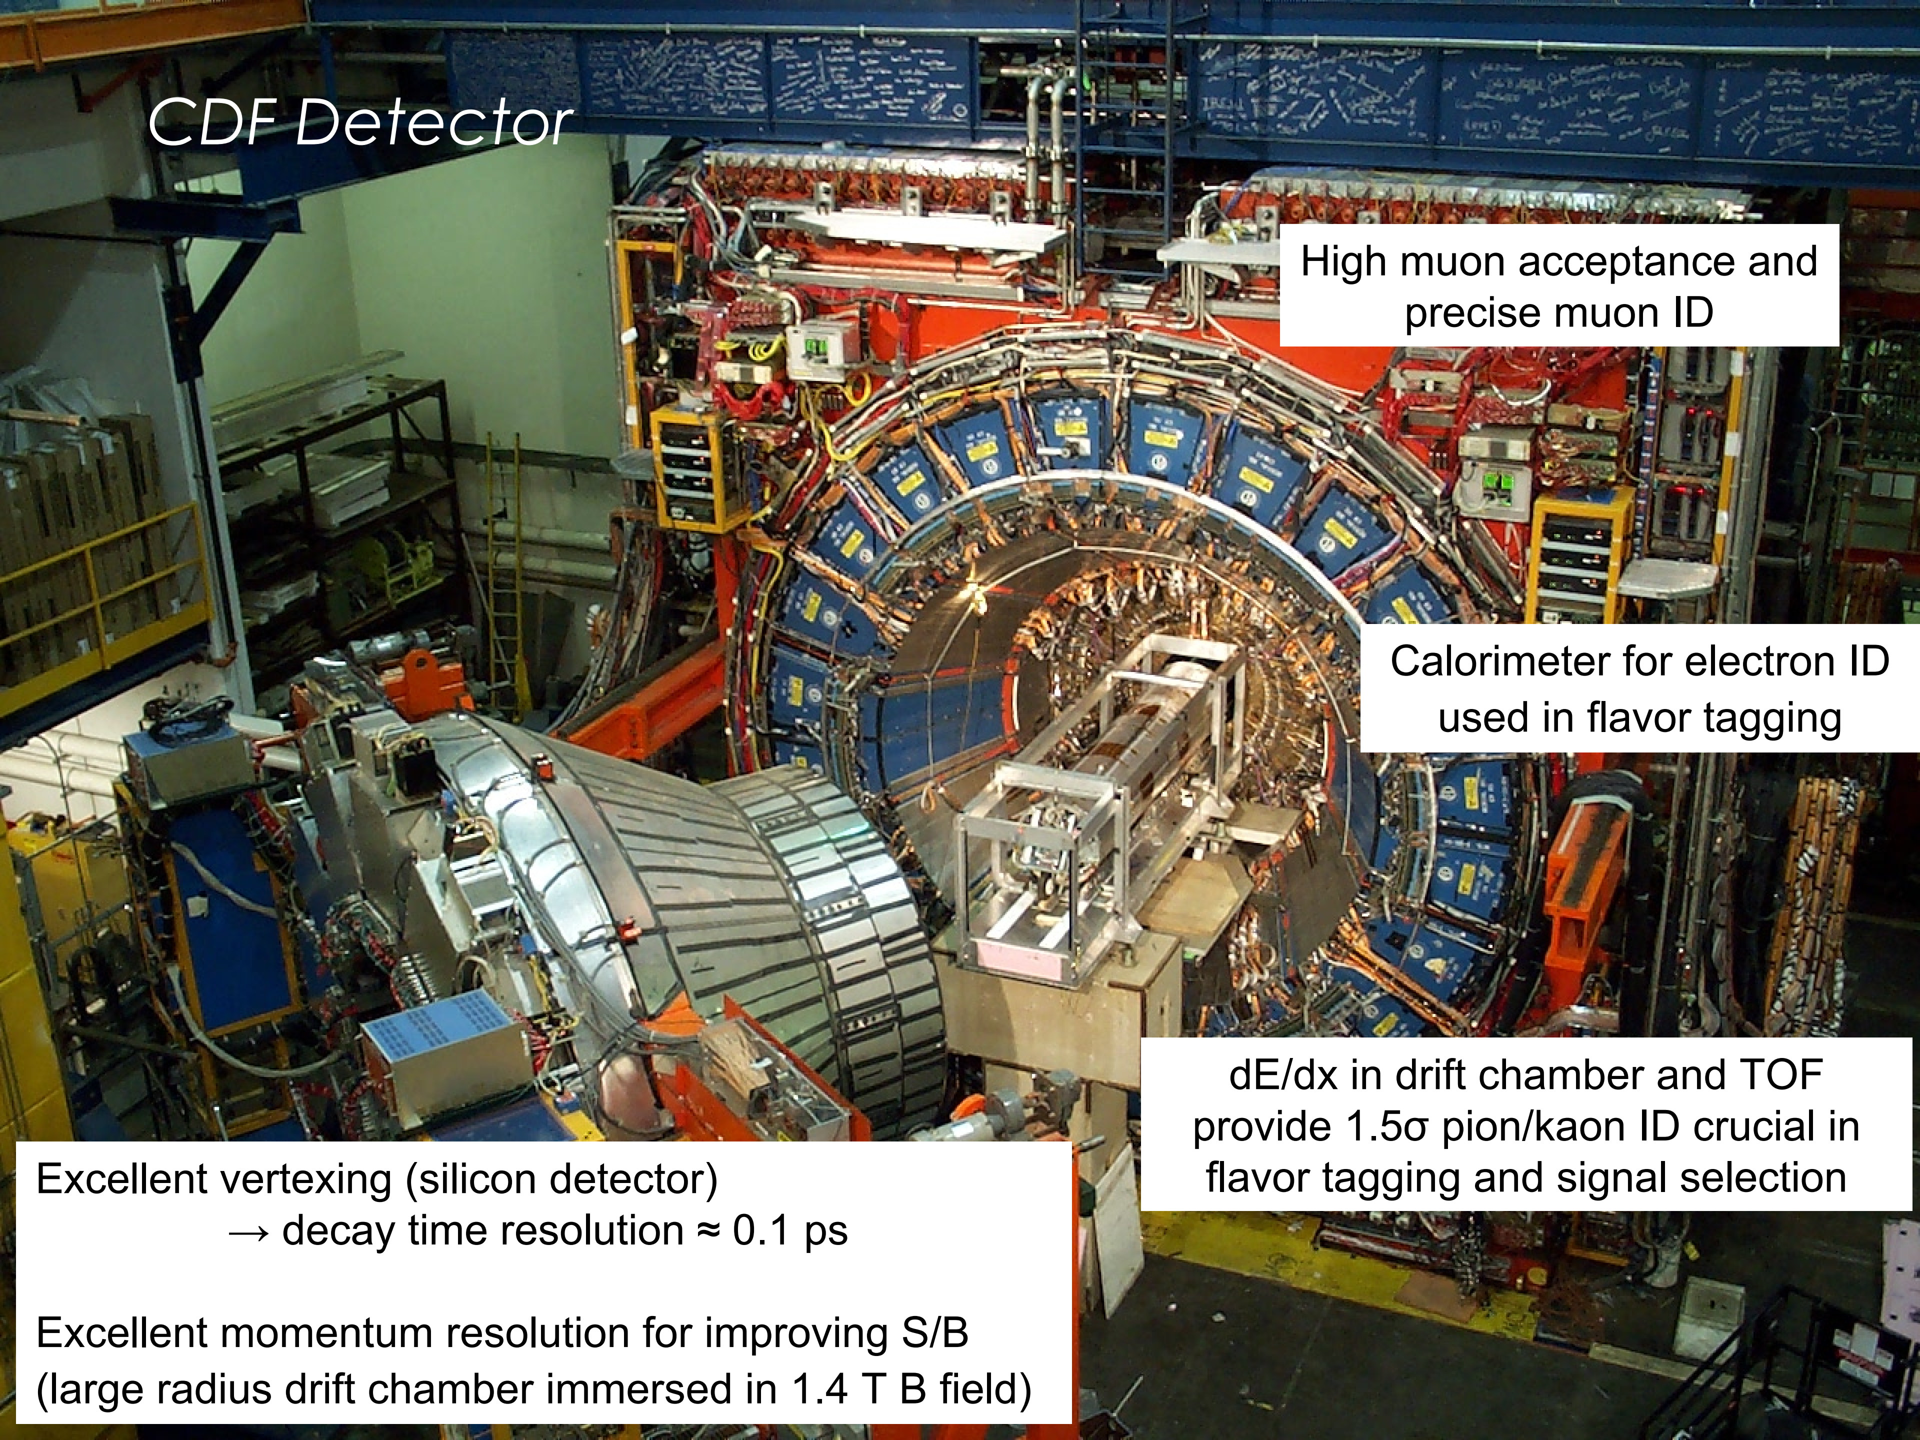


Status Before This Update: CDF + DØ Combination

- CDF + DØ combination done by the Tevatron B Working Group:
http://tevbwg.fnal.gov/

- Shows intriguing 2.1σ deviation from SM expectation (CDF note 9787)



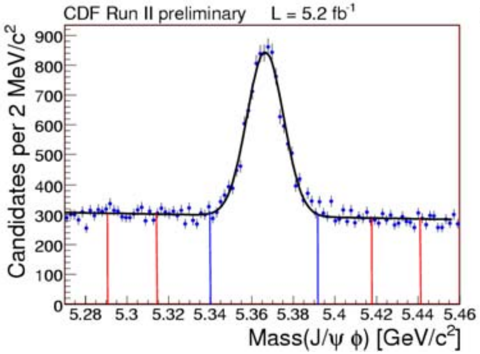


CDF Detector
High muon acceptance and precise muon ID
Calorimeter for electron ID used in flavor tagging
dE/dx in drift chamber and TOF provide 1.5σ pion/kaon ID crucial in flavor tagging and signal selection
Excellent vertexing (silicon detector) → decay time resolution ≈ 0.1 ps
Excellent momentum resolution for improving S/B (large radius drift chamber immersed in 1.4 T B field)

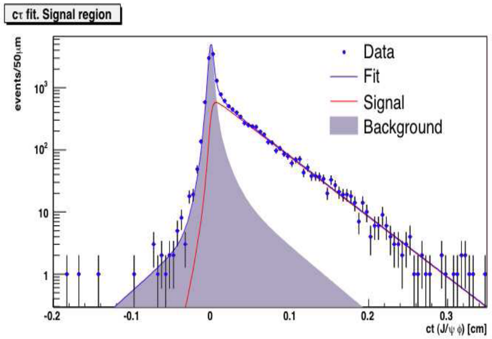
Analysis Components

- Multi-dimensional likelihood fit

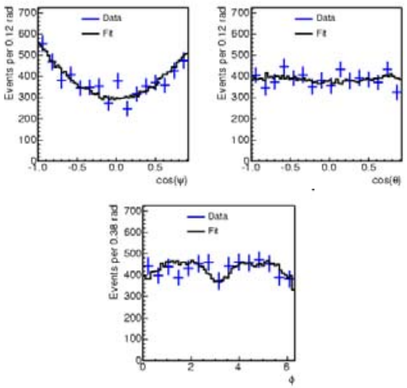
$$f_s P_s(m|\sigma_m) P_s(t, \vec{\rho}, \xi | \mathcal{D}, \sigma_t) P_s(\sigma_t) P_s(\mathcal{D})$$



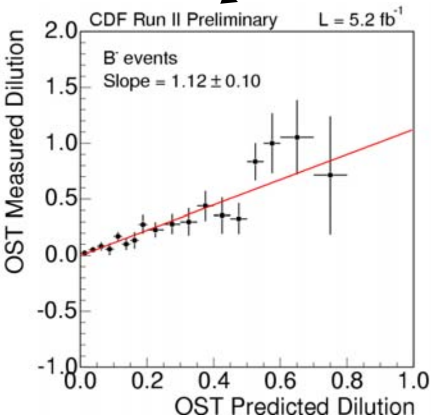
Mass
discriminate signal against background



Decay-time
determines lifetime of each mass eigenstate



Angles
separate CP-even from CP-odd final states



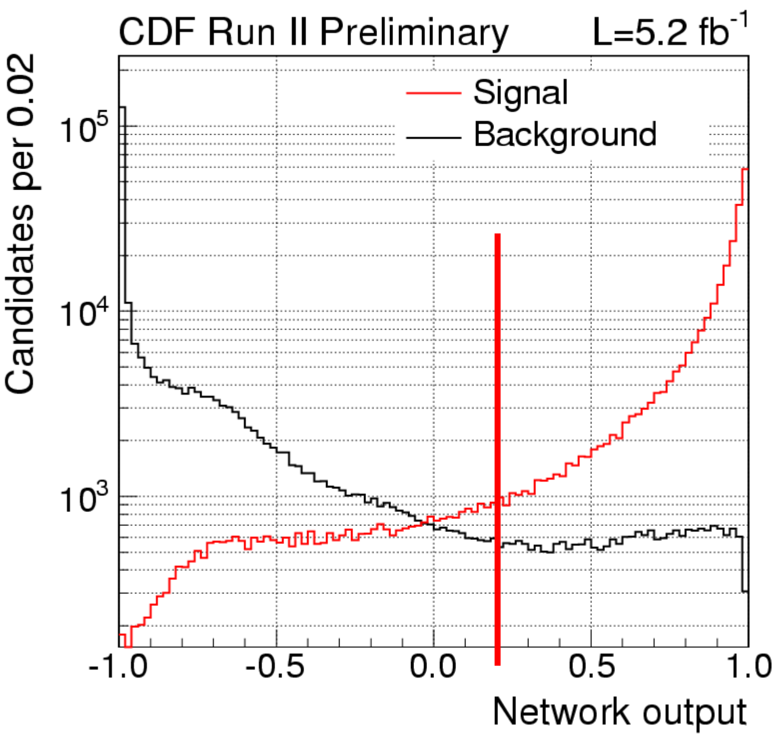
Tagging
determines flavor of initial B_s state

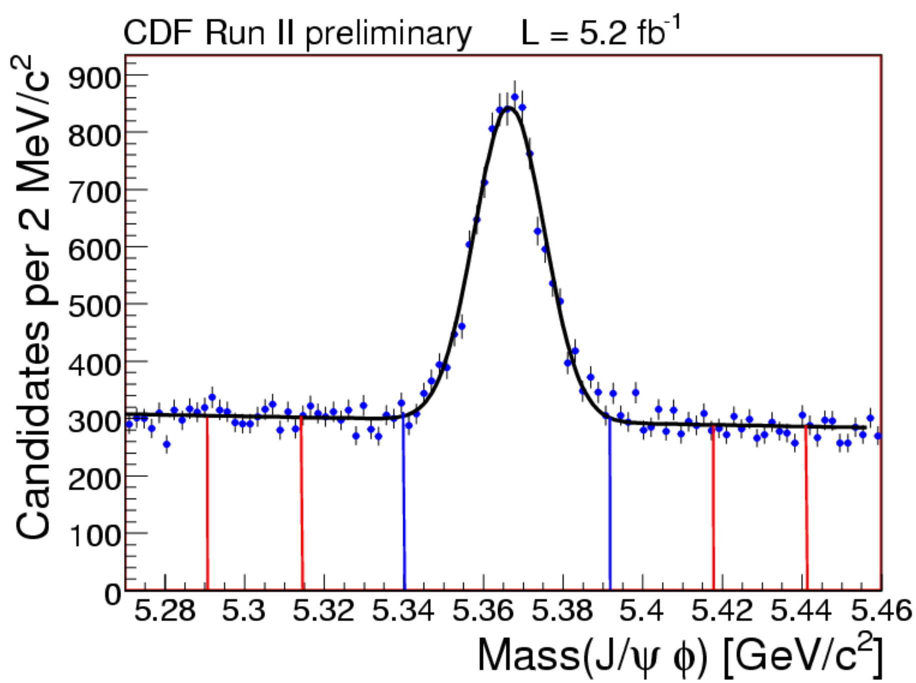
Signal Reconstruction

- Reconstruct $B^0_s \rightarrow J/\psi\Phi$ in 5.2 fb^{-1} of data from sample selected by di-muon trigger

- Combine kinematic variables with particle ID information (dE/dx, TOF) in neural network to discriminate signal from background

- Yield of ~6500 signal B_s events with *S/B ~ 1* (compared to ~3150 in 2.8 fb^{-1})





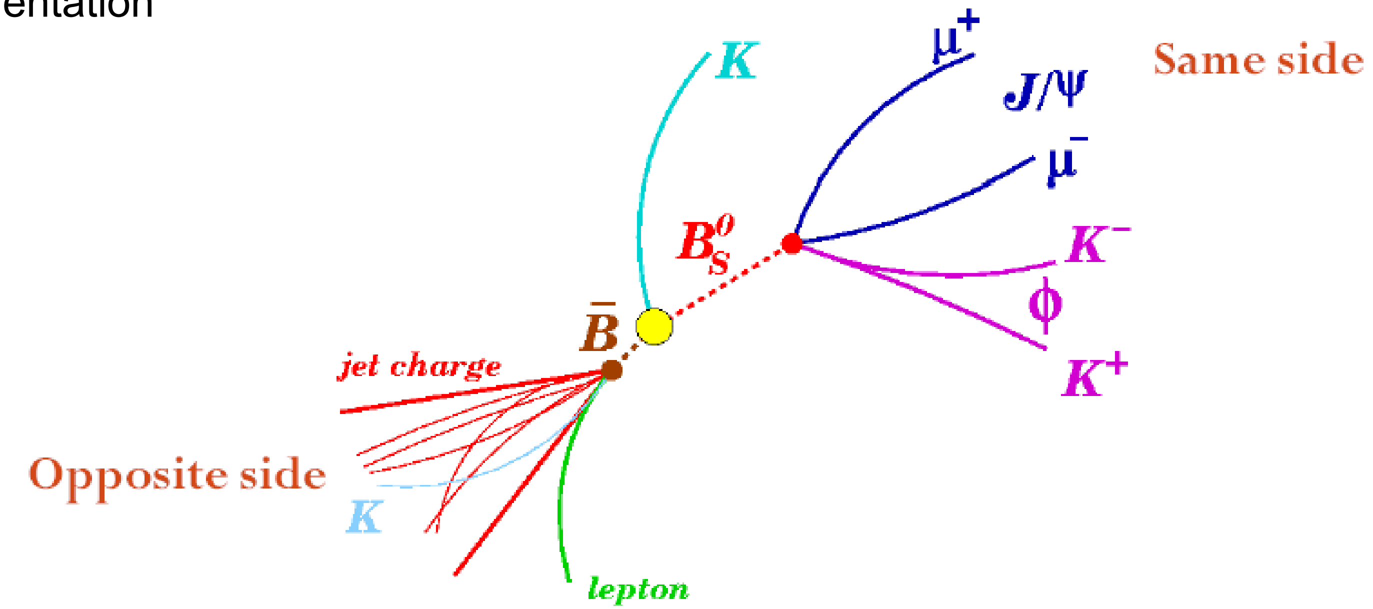
Flavor Tagging

- Tevatron: *b*-quarks mainly produced in pairs of *bottom anti-bottom*

→ flavor of the *B* meson at production inferred with:

- Opposite Side Tagger (OST): exploits decay products of other *b*-hadron in the event

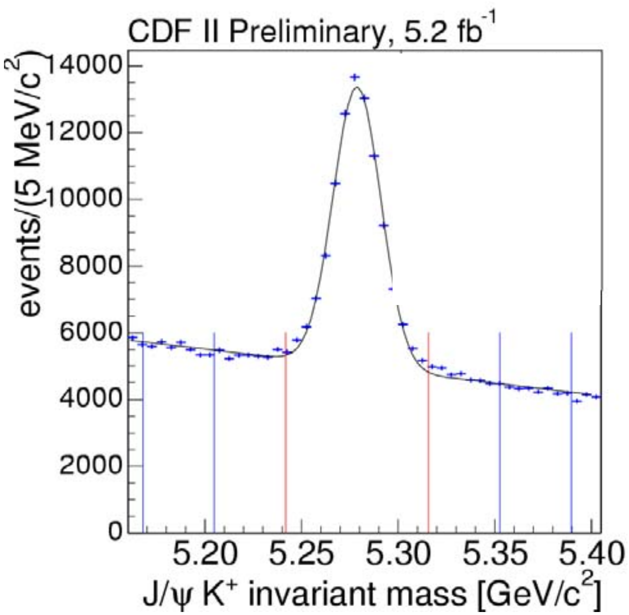
- Same Side Kaon Tagger (SSKT): exploits correlations with particles produced in fragmentation

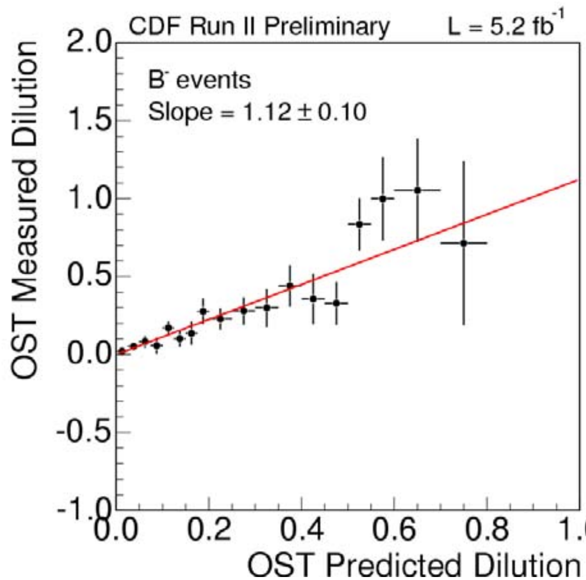


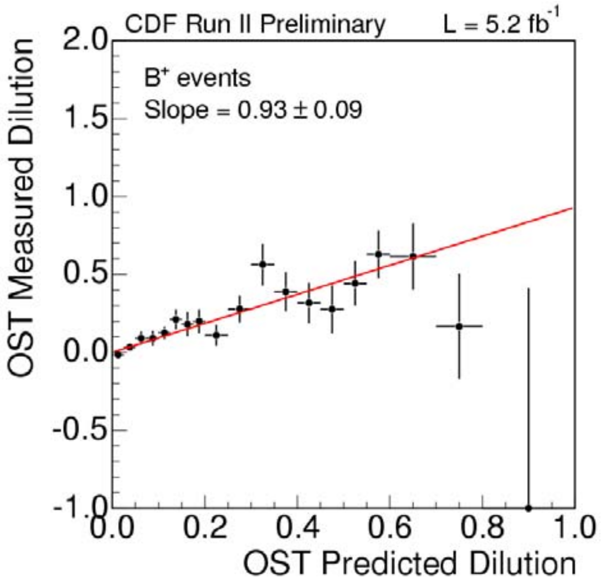
- Output of flavor tagger:
  - flavor decision (*b*-quark or anti-*b*-quark)
  - probability that the decision is correct: $P = (1 + Dilution) / 2$

Opposite Side Tagging Calibration and Performance

- OST combines in a NN opposite side lepton and jet charge information
- Initially calibrated using a sample of inclusive semileptonic *B* decays
    - predicts tagging probability on event-by-event basis
- Re-calibrated using ≈ 52,000 $B^{+/-} \rightarrow J/\Psi\ K^{+/-}$ decays







- OST efficiency = 94.2 +/- 0.4%, OST dilution = 11.5 +/- 0.2 % (correct tag probability ~56%)
- Total tagging power = 1.2%

Same Side Tagging Calibration

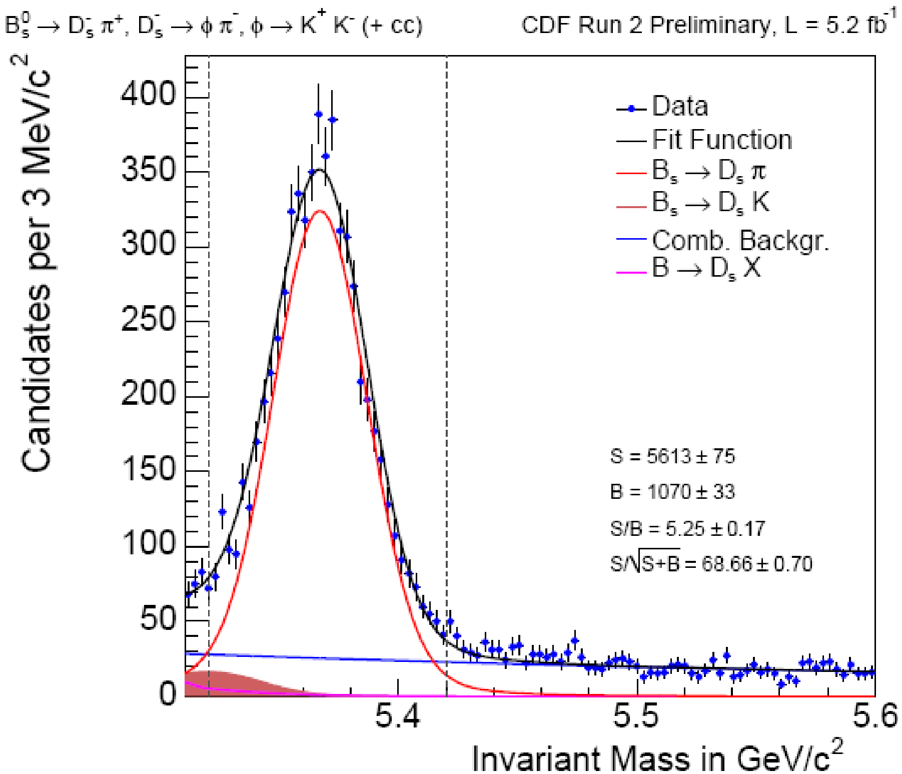
- Event-by-event predicted dilution based on simulation
- Calibrated with 5.2 fb^{-1} of data
- Simultaneously measuring the B_s mixing frequency Δm_s and the dilution scale factor A

$$P_{Sig}(ct|\sigma_{ct}, \xi = \xi_D \cdot \xi_P, D) = \frac{1}{N} \cdot \left[\frac{1}{\tau} e^{-\tilde{t}/\tau} \cdot (1 + \xi \mathcal{A} D \cdot \cos(\Delta m_s \tilde{t}))\right] \otimes \mathcal{G}(c\tilde{t}|\sigma_{ct}) \cdot \epsilon(ct|\sigma_{ct})$$

- D – event by event predicted dilution
- ξ – tagging decision = +1, -1, 0 for B_s, $\overline{B}_s$ and un-tagged events

- Fully reconstructed B_s decays selected by displaced track trigger

Decay Channel	S
$B_s^0 \to D_s^- \pi^+,\ D_s^- \to \phi\pi^-$	5613 ± 75
$B_s^0 \to D_s^- \pi^+,\ D_s^- \to K^* K^-$	2761 ± 53
$B_s^0 \to D_s^- \pi^+,\ D_s^- \to (3\pi)^-$	2652 ± 52
$B_s^0 \to D_s^- (3\pi)^+,\ D_s^- \to \phi\pi^-$	1852 ± 43
Sum	$\mathbf{12877 \pm 113}$



Same Side Tagging Performance

- B_s oscillation frequency measured $\Delta m_s = (17.79 \pm 0.07)\ \mathrm{ps}^{-1}$ (statistical error only)

- In good agreement with the published CDF measurement with 1 fb^{-1}
PRL 97, 242003 2006, PRL 97, 062003 2006

$$\Delta m_s = 17.77\ \pm 0.10\ (\mathrm{stat})\ \pm 0.07\ (\mathrm{syst})\ \mathrm{ps}^{-1}$$

used as external constraint in β_s measurement

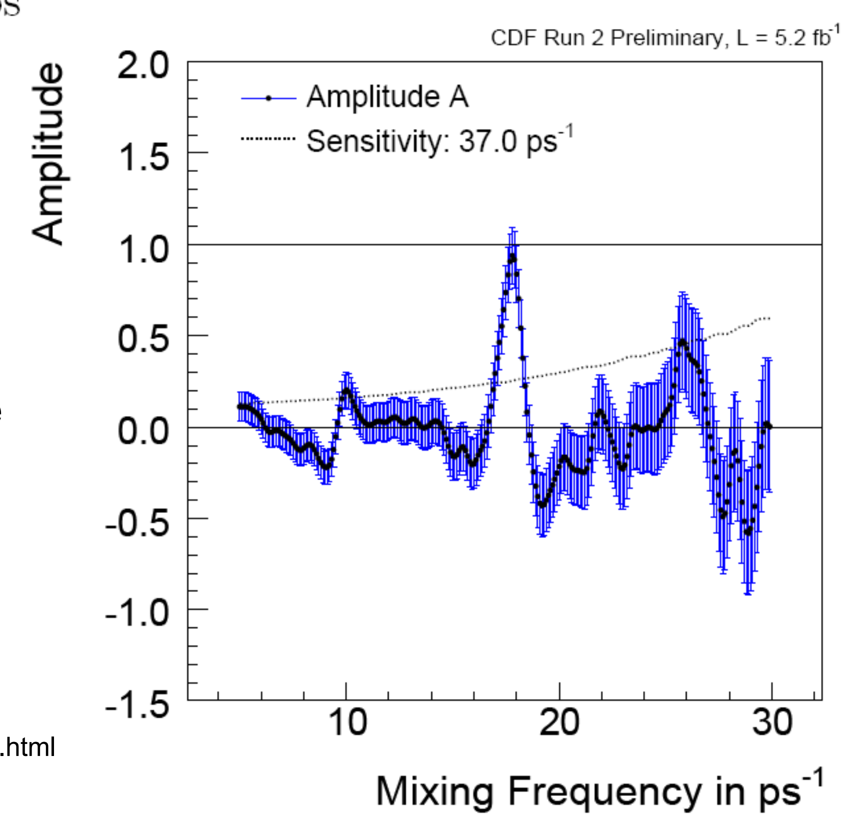
- Dilution scale factor (amplitude) in good agreement with 1:

$$\mathcal{A} = 0.94 \pm 0.15\ (stat.) \pm 0.13\ (syst.)$$

- Largest systematic uncertainty from decay time resolution modeling

- Total SSKT tagging power:

$$\varepsilon \mathcal{A}^2 D^2 = (3.2 \pm 1.4)\ \%$$



http://www-cdf.fnal.gov/physics/new/bottom/100204.blessed-sskt-calibration/index.html
CDF public note 10108

Detector Angular Efficiency

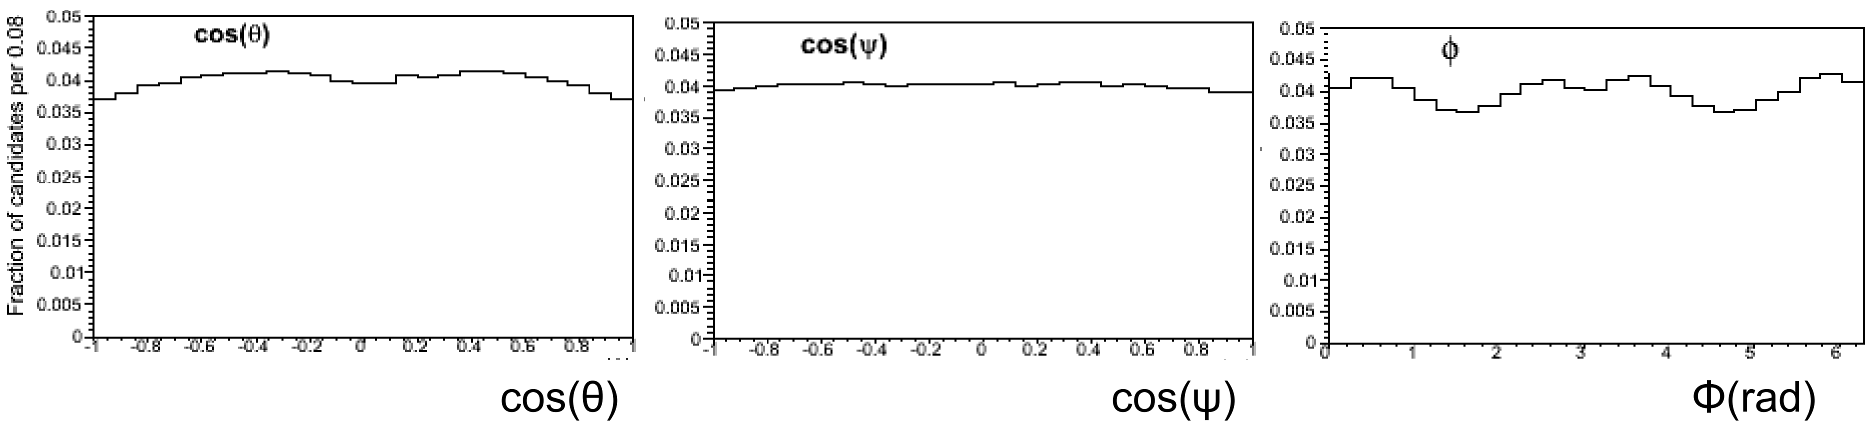
- *CP even* and *CP odd* final states have different angular distributions

  → use angles $\rho = (\theta, \phi, \psi)$ to statistically separate *CP even* and *CP odd* components

- Detector acceptance distorts the angular distributions

  → determine 3D angular efficiency function from simulation and account for this effect in the fit

CDF Simulation of Detector Angular Sculpting



B_s Lifetime and Decay Width Difference

- Assuming no *CP* violation ($\beta_s = 0$) obtain most precise measurements of lifetime τ_s and decay width difference $\Delta\Gamma_s$:

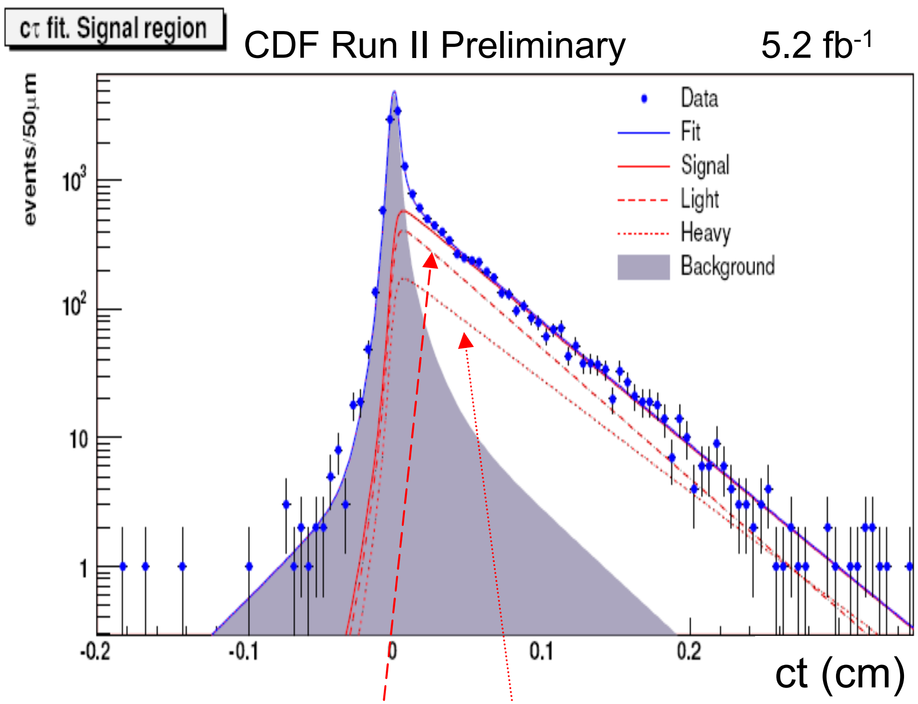
$$\tau_s = 1.53 \pm 0.025 \text{ (stat.) } \pm 0.012 \text{ (syst.) ps}$$

$$\Delta\Gamma = 0.075 \pm 0.035 \text{ (stat.)} \pm 0.01 \text{ (syst.) } ps^{-1}$$

compared to PDG 2009 averages:

$\tau_s = 1.472^{+0.024}_{-0.026}$ ps

$\Delta\Gamma_s = 0.062^{+0.034}_{-0.037}$ ps^{-1}



CP-even (B_s^{light}) and *CP*-odd (B_s^{heavy}) components have different lifetimes

$\rightarrow \Delta\Gamma \neq 0$

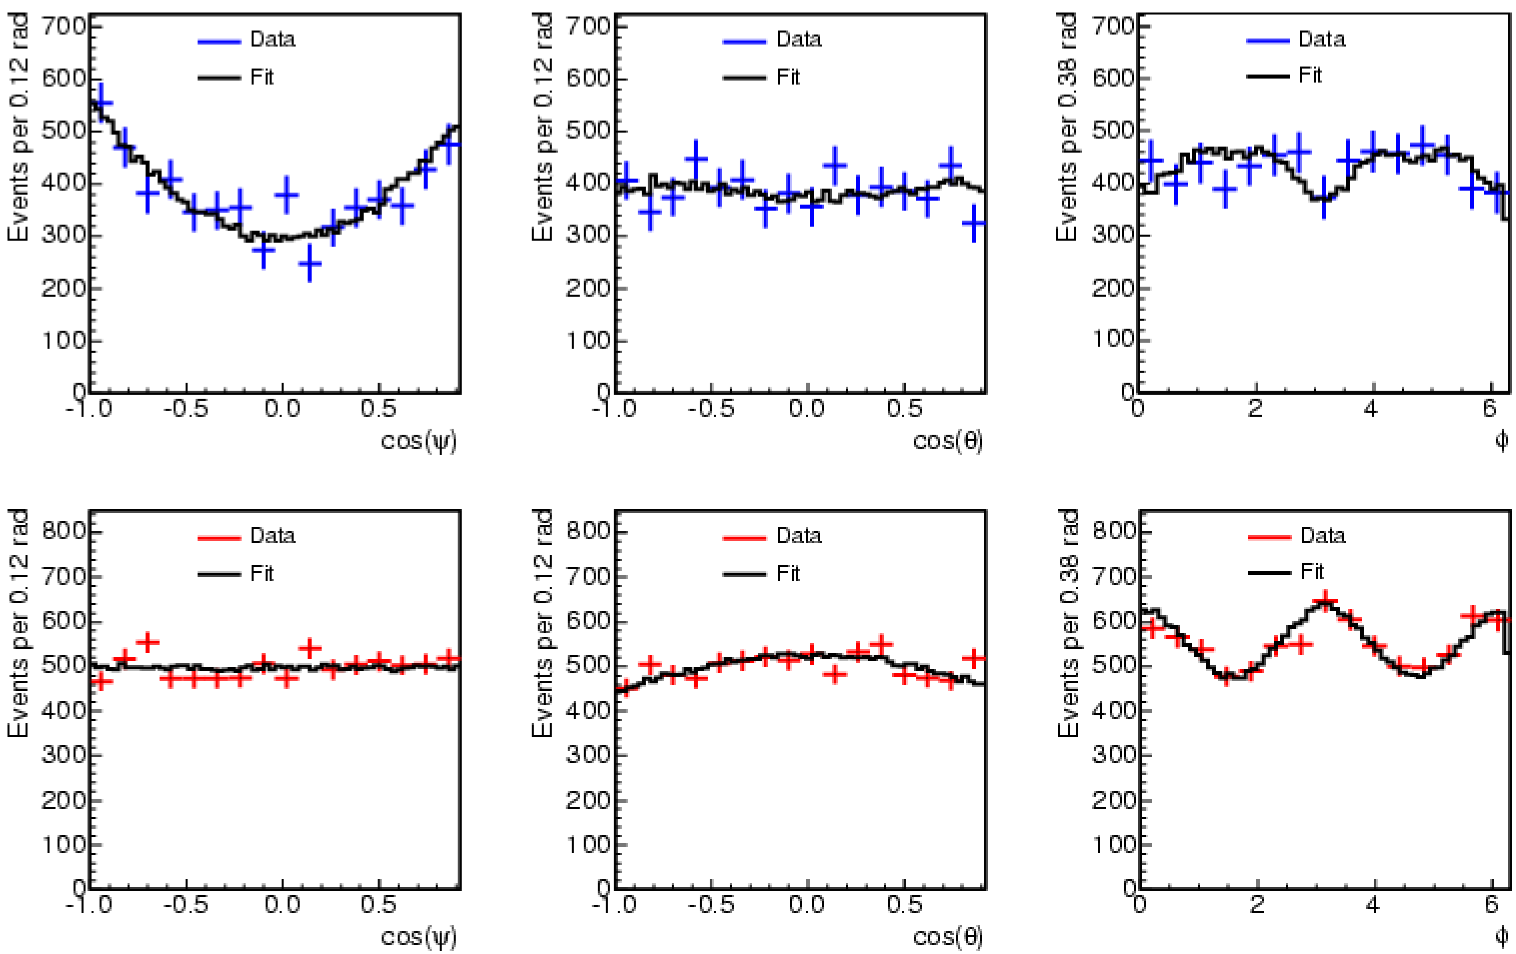
Polarization Amplitudes

Most precise measurement of polarization amplitudes

$$|A_{\parallel}(0)|^2 = 0.231 \pm 0.014\ (\text{stat}) \pm 0.015\ (\text{syst.})$$
$$|A_0(0)|^2 = 0.524 \pm 0.013\ (\text{stat}) \pm 0.015\ (\text{syst.})$$
$$\phi_{\perp} = 2.95 \pm 0.64\ (\text{stat}) \pm 0.07\ (\text{syst.}).$$

Signal fit projections

Background fit projections



S-Wave

- As noted in arxiv:0812.2832v3, the KK pair in $B_s \to J/\Psi\ KK$ decays can be in an s-wave state with ~6% contribution in a +/-10 MeV window around the Φ peak

- Systematic effects from neglecting such contribution were first investigated by Clarke *et al* in arxiv:0908.3627v1 where it is shown that:
    - 10% un-accounted s-wave contamination in the Φ region leads to
        - 10% bias in the measured $2\beta_s$, towards the SM prediction
        - 15% increase in statistical errors

- S-wave contribution can be either non-resonant or from the $f^0(980)$ resonance

- To account for potential s-wave contribution, enhance the likelihood function to account for the s-wave amplitude A_S and interference between s-wave and p-wave

- Time dependence of the s-wave amplitude A_S is *CP-odd*, same as $A_\perp$

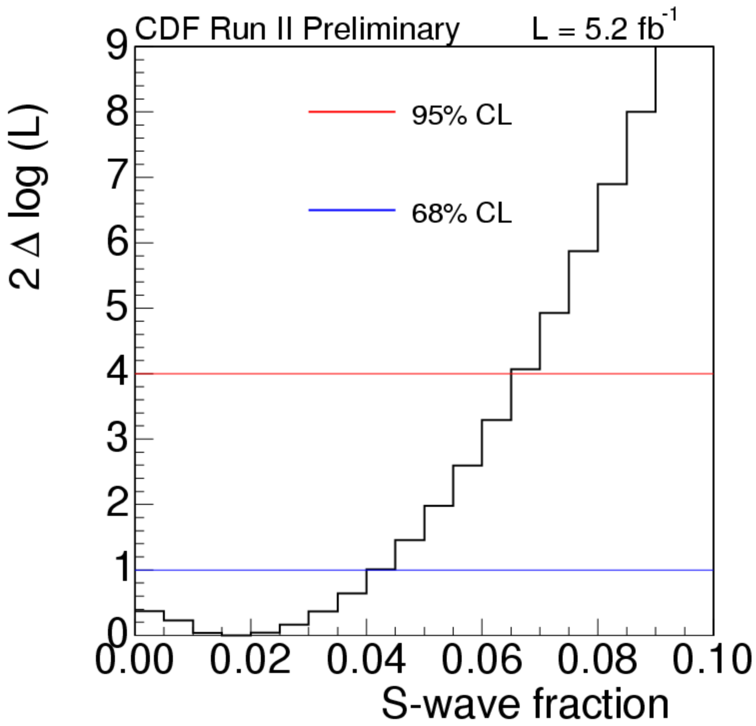
- Mass and phase of s-wave component are assumed flat (good approximation in a narrow +/- 10 MeV around the Φ mass)

S-Wave Measurement

- The fitted s-wave fraction is found to be very small in the KK mass range used in this analysis: [1.009, 1.028] GeV

s-wave fraction < 6.7% at 95% C.L.

- To be compared with expectation from arxiv:0812.2832v3 of 6.3% s-wave contribution in a range of +/- 10 MeV around the Φ peak



CP Violation Phase β_s in Tagged $B_s \rightarrow J/\Psi\Phi$ Decays

- Without the s-wave the likelihood function is symmetric under the transformation

$$2\beta_s \rightarrow \pi - 2\beta_s \qquad \Delta\Gamma \rightarrow -\Delta\Gamma$$

$$\delta_{||} \rightarrow 2\pi - \delta_{||} \qquad \delta_{\perp} \rightarrow \pi - \delta_{\perp}$$

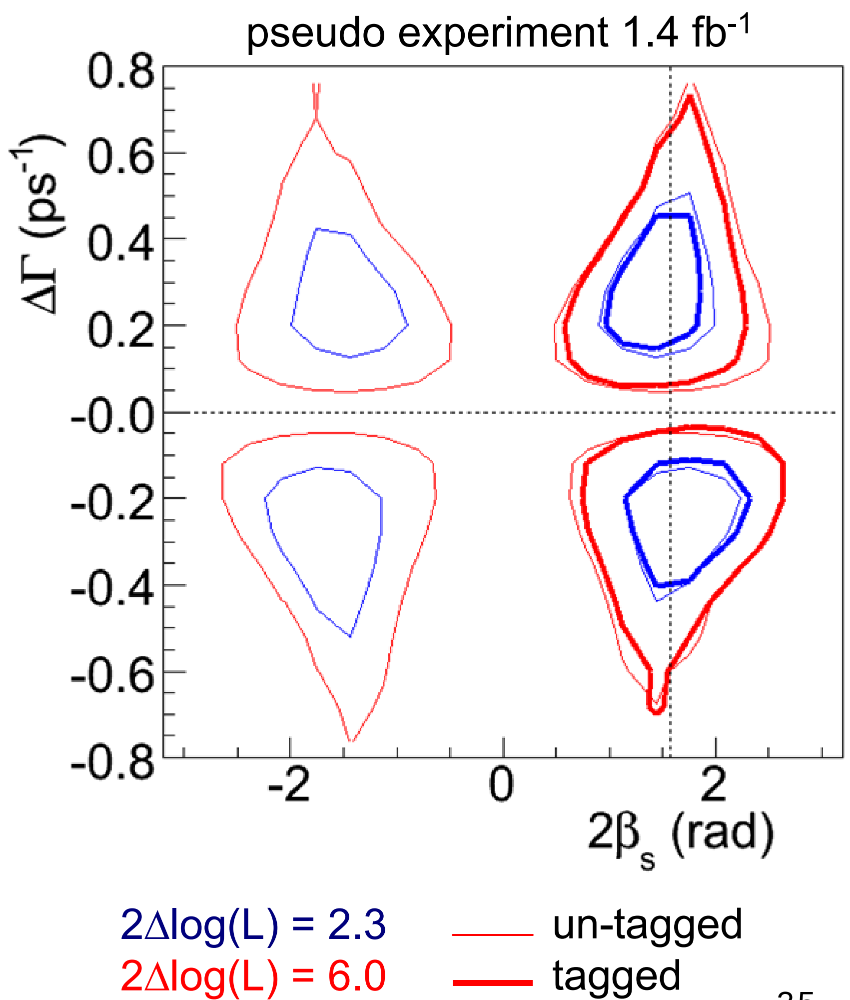
- Study expected effect of tagging using pseudo-experiments

- Improvement of parameter resolution is small due to limited tagging power ($\varepsilon D^2 \sim 4.5\%$ compared to B factories ~30%)

- However, $\beta_s \rightarrow -\beta_s$ no longer a symmetry $\rightarrow$ 4-fold ambiguity reduced to 2-fold ambiguity

- Adding the s-wave "slightly" breaks the symmetry due to asymmetric Φ mass shape

- Symmetry still valid with good approximation…



CP Violation Phase β_s in Tagged $B_s \rightarrow J/\Psi\Phi$ Decays

- Without the s-wave the likelihood function is symmetric under the transformation

$$2\beta_s \rightarrow \pi - 2\beta_s \qquad \Delta\Gamma \rightarrow -\Delta\Gamma$$

$$\delta_{||} \rightarrow 2\pi - \delta_{||} \qquad \delta_{\perp} \rightarrow \pi - \delta_{\perp}$$

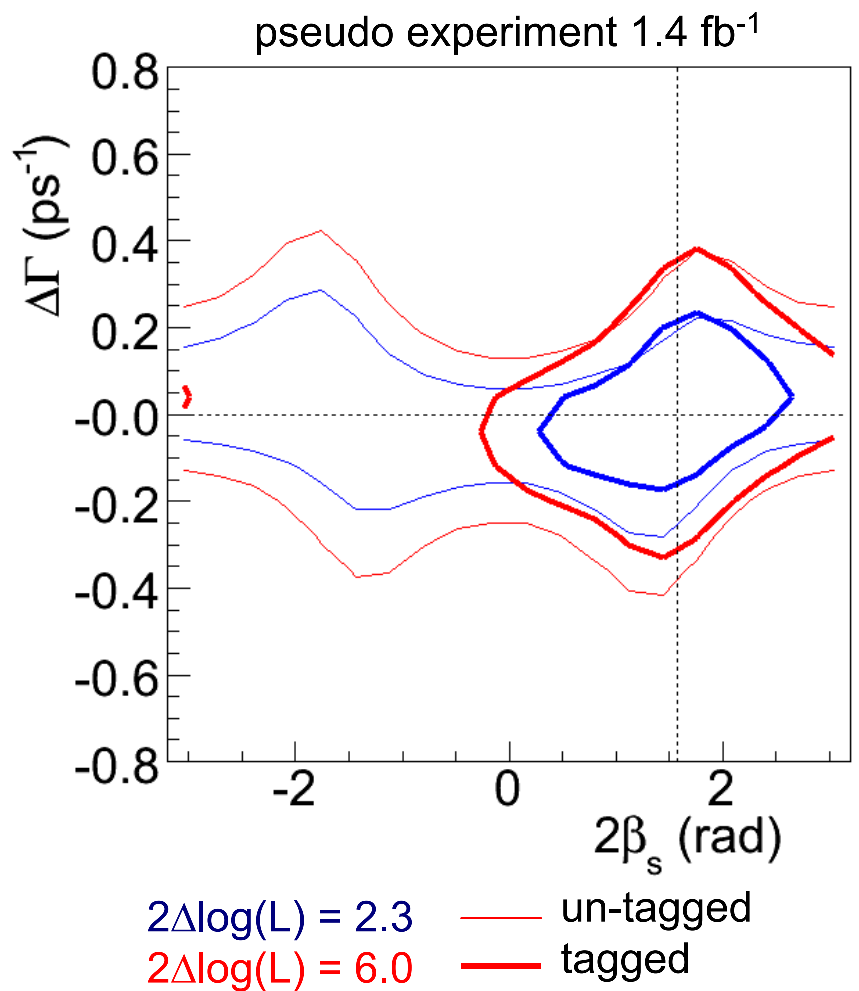
- Study expected effect of tagging using pseudo-experiments

- Improvement of parameter resolution is small due to limited tagging power ($\varepsilon D^2 \sim 4.5\%$ compared to B factories ~30%)

- However, $\beta_s \rightarrow -\beta_s$ no longer a symmetry $\rightarrow$ 4-fold ambiguity reduced to 2-fold ambiguity

- Adding the s-wave "slightly" breaks the symmetry due to asymmetric Φ mass shape

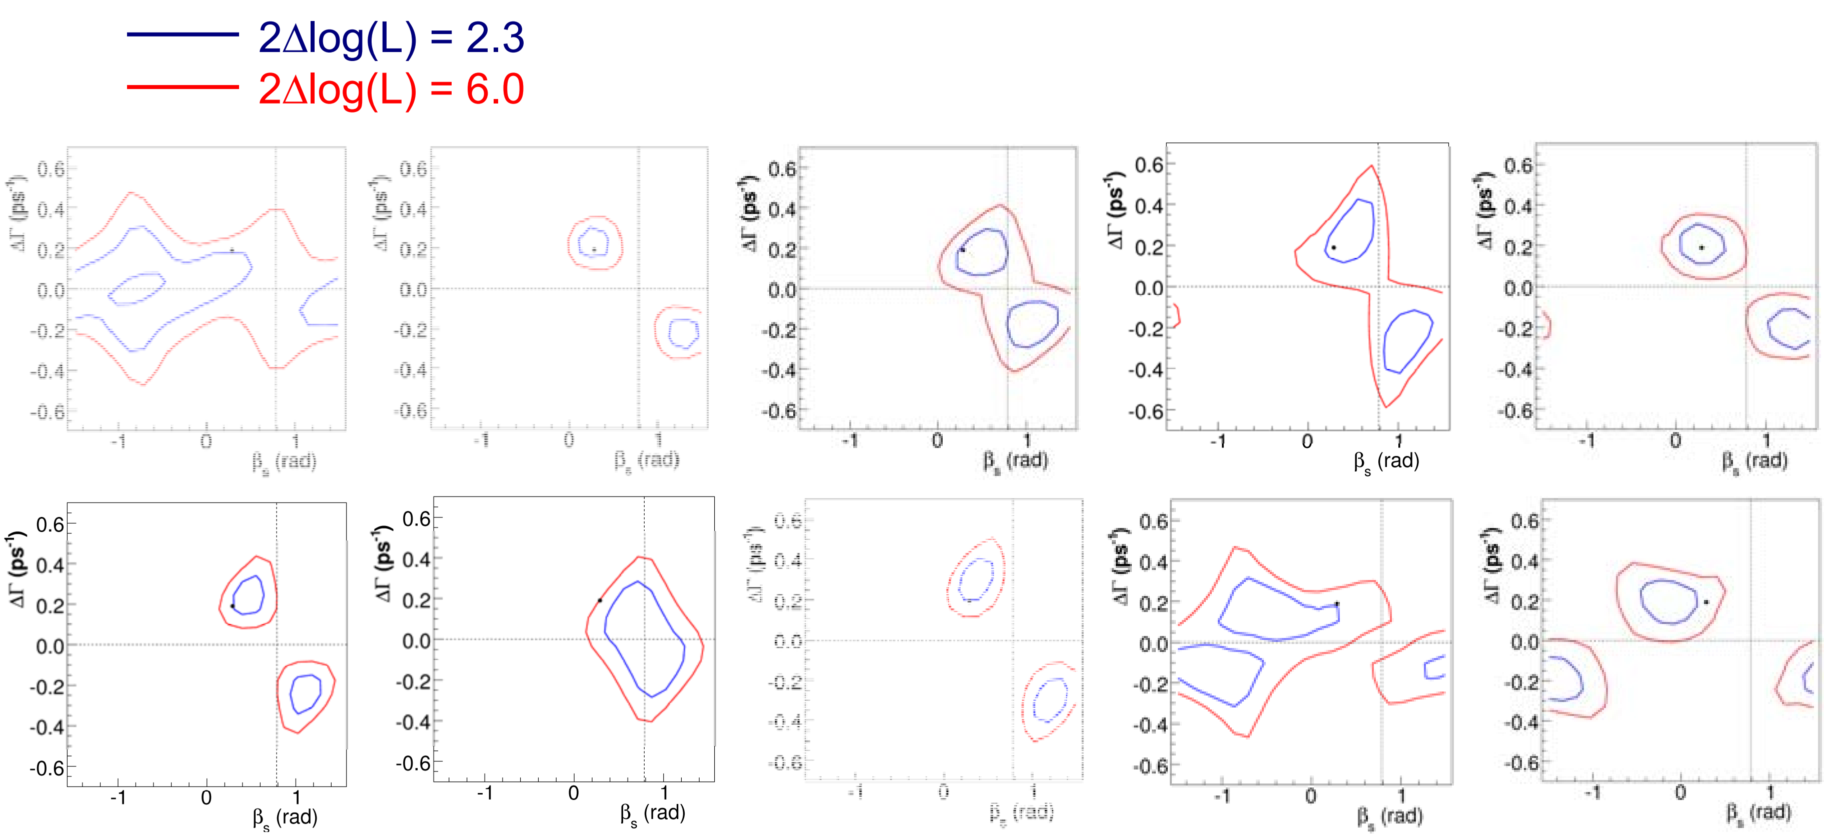
- Symmetry still valid with good approximation



Cross Checks With Pseudo-Experiments

- Generate 10 pseudo-experiments with β_s = 0.3 and $\Delta\Gamma$ = 0.2 corresponding to 1.4 fb^{-1}
    - same parameters, just different random seeds

- Large fluctuations expected in shape and size of confidence regions



Non-Gaussian Regime

- Pseudo-experiments show that we are still not in perfect Gaussian regime
  → *quote confidence regions instead of point estimates*

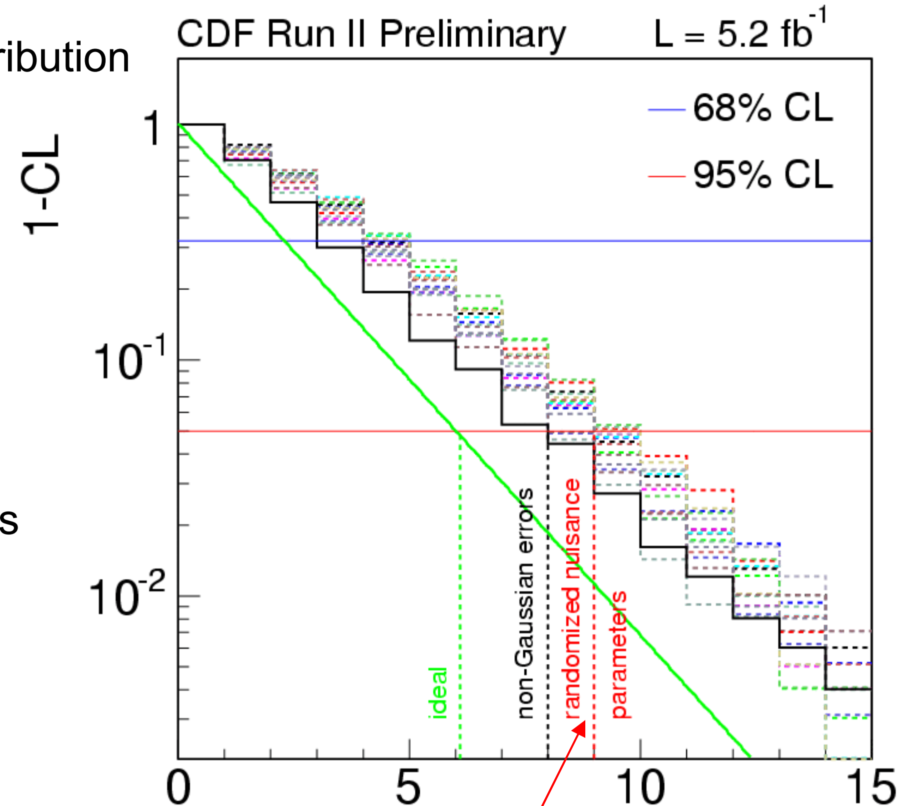
- In ideal case (high statistics, Gaussian likelihood), to get the 2D 68% (95%) C.L. regions, take a slice through profiled likelihood at 2.3 (6.0) units up from minimum

- In this analysis integrated likelihood ratio distribution (black histogram) deviates from the ideal χ^2 distribution (green continuous curve)

- Using pseudo-experiments establish a "map" between Confidence Level and $2\Delta\log(L)$

- All nuisance parameters are randomly varied within +/- 5σ from their best fit values and maps of CL vs $2\Delta\log(L)$ re-derived

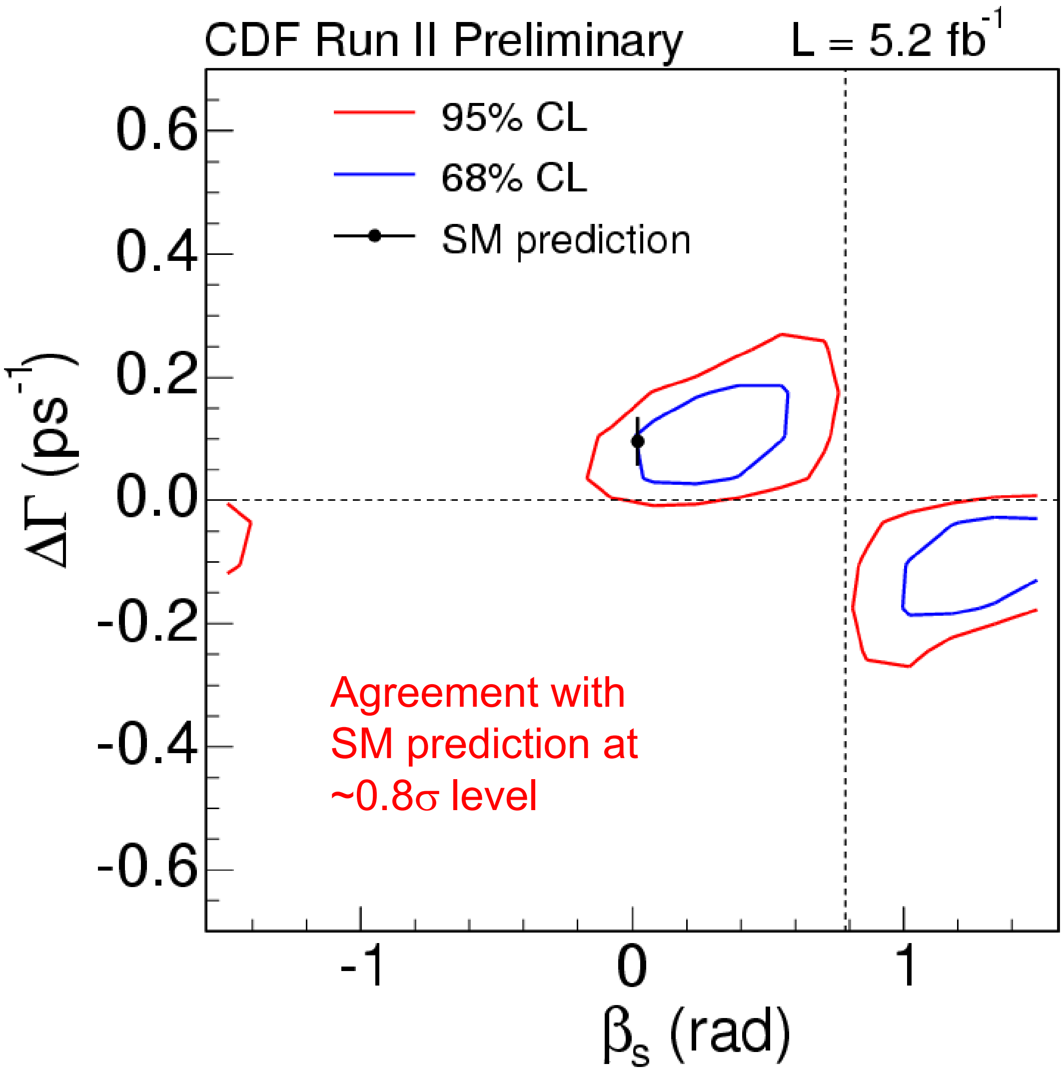
- To establish final confidence regions use most conservative case



non-Gaussian correction for wide variations of nuisance parameters

CP Violation Phase β_s with 5.2 fb^{-1} at CDF

- Final confidence regions in β_s-$\Delta\Gamma_s$ space:

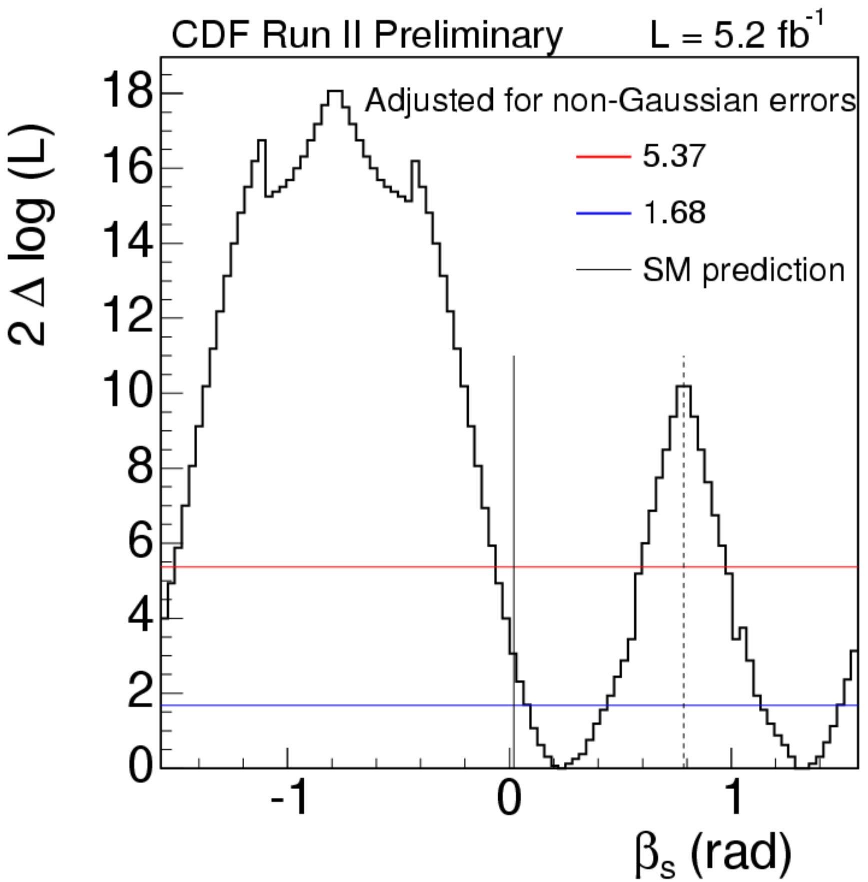


1D Profiled Likelihood for β_s

- CP violation phase bs is bounded by the ranges:

[0.02, 0.52] U [1.08, 1.55] at 68% C.L.

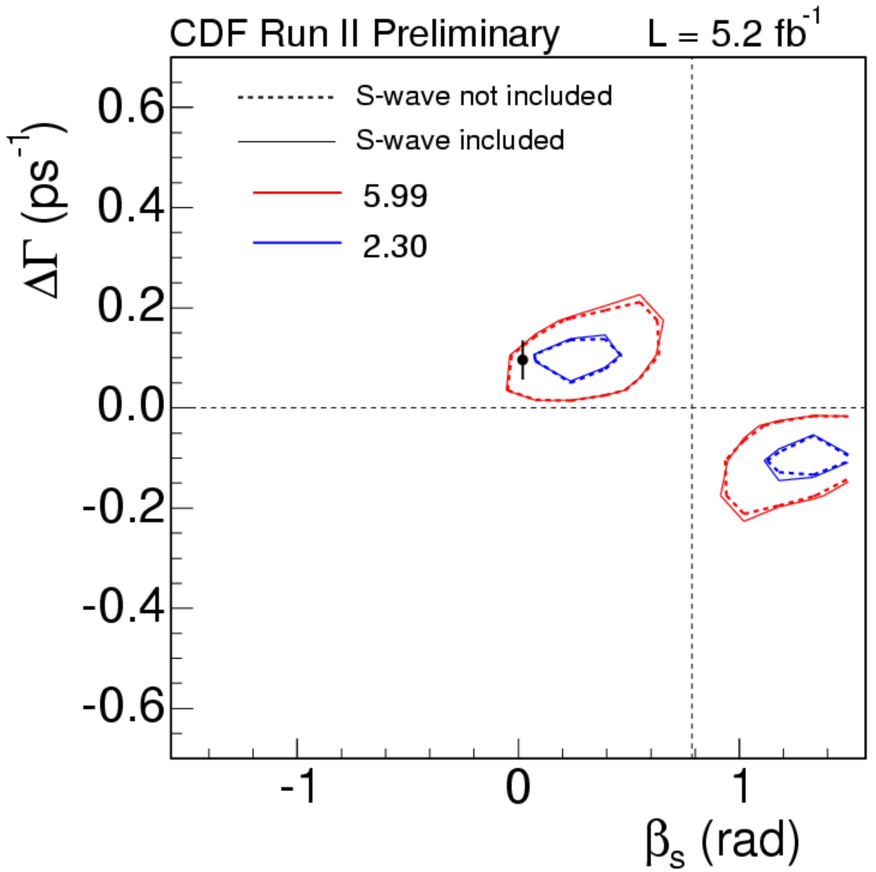
[-π/2, -1.44] U [-0.13, 0.68] U [0.89, π/2] at 95% CL



Agreement with SM at ~1σ level

β_s-$\Delta\Gamma$ Contours with and without Including the S-Wave

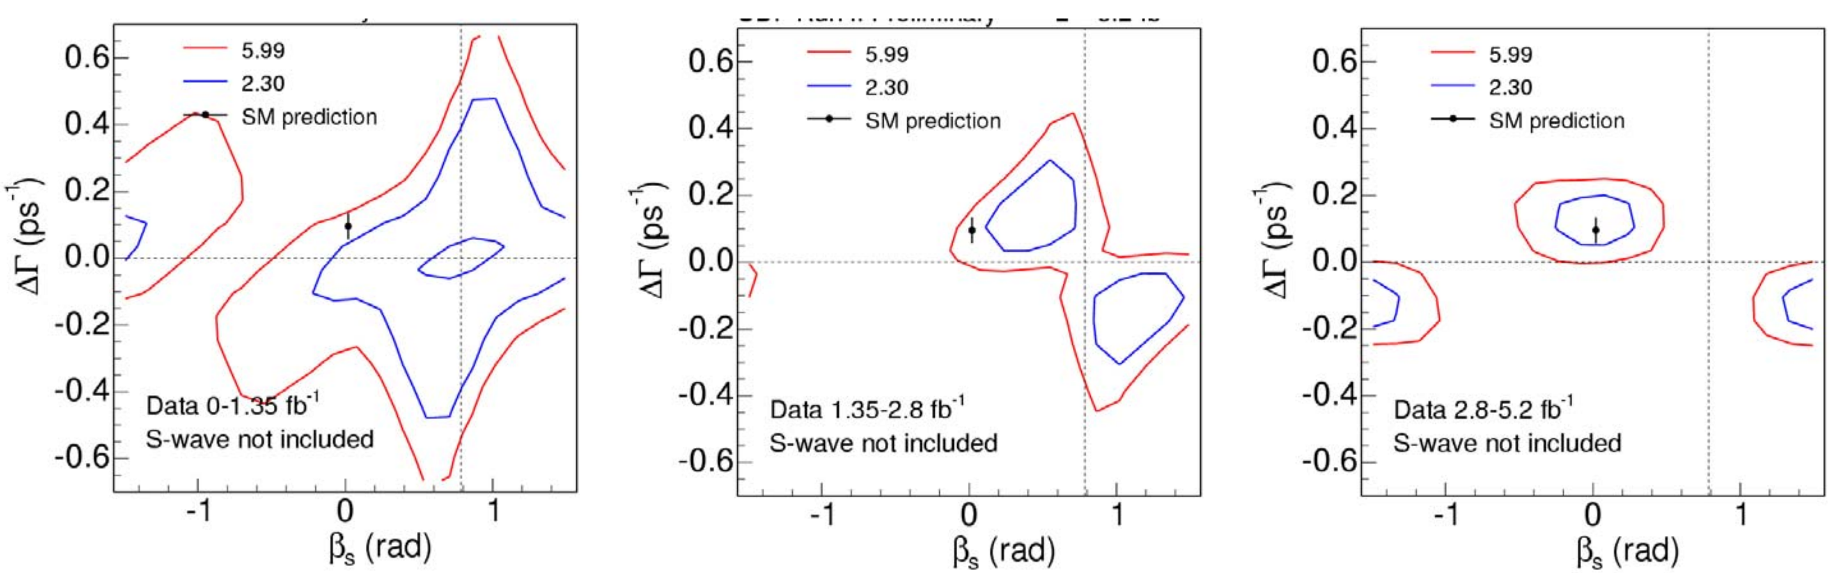
- Compare likelihood contours with and without including the s-wave
- Very small effect on β_s and $\Delta\Gamma$



Comparison Between Different Data Periods

- Divide 5.2 fb^{-1} sample in three sub-samples corresponding to three public releases:
    - 0 - 1.4 fb^{-1} (initial result released at the end of 2007, PRL 100, 161802 (2008), arXiv:0712.2397)
    - 1.4 - 2.8 fb^{-1} (added for 2008 ICHEP update)
    - 2.8 - 5.2 fb^{-1} (added for this update)

- Previous results reproduced with updated analysis
- Clearly, improved agreement with the SM expectation comes from the second half of data (2.8 – 5.2 fb^{-1})

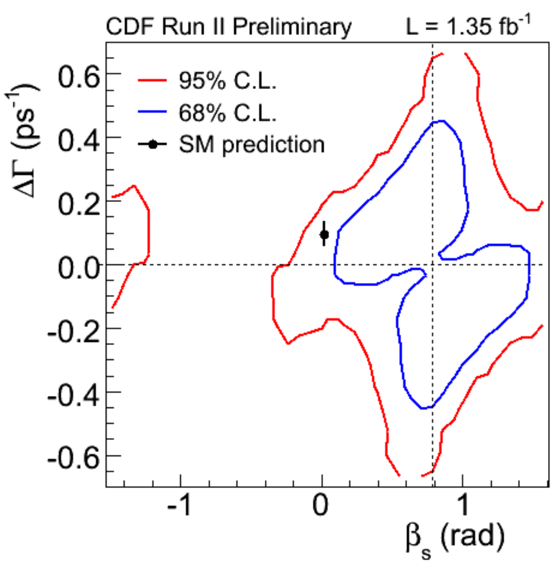


Comparison with Previous Results

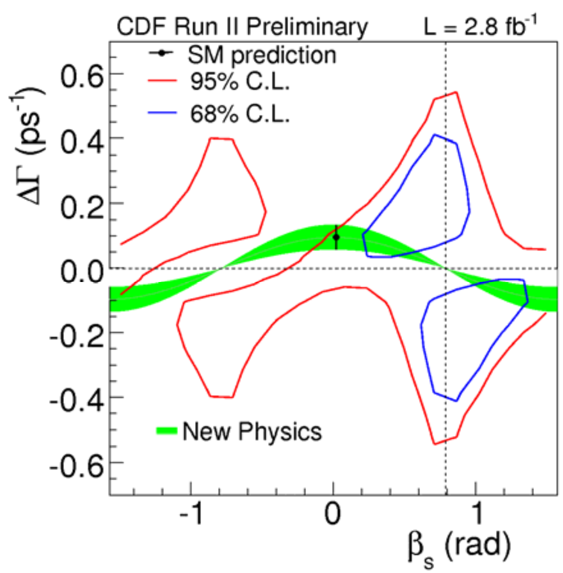
– β_s and $\Delta\Gamma_s$ allowed parameter space greatly reduced

- Agreement with SM expectation improves with higher statistics

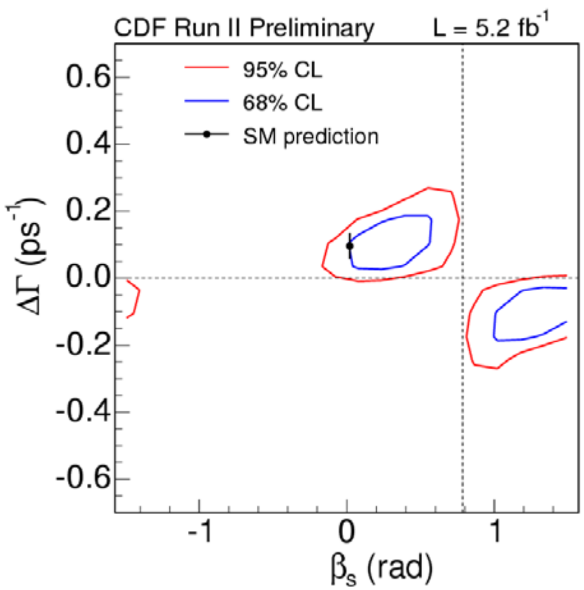
Initial result released at the end of 2007, PRL 100, 161802 (2008) arXiv:0712.2397
~2000 signal events



2008 ICHEP update with preliminary PID and tagging
~3150 signal events



This update
~6500 signal events



Conclusions

- Measurement of CP violation in B_s system updated by CDF with 5.2 fb^{-1}

- Tightened constraints in β_s space:

[0.02, 0.52] U [1.08, 1.55] at 68% C.L.

- Improved agreement with SM expectation, at ~1σ level

- Best measurements of B_s lifetime, decay width difference $\Delta\Gamma_s$ and polarization amplitudes

$c\tau_s$ = 458.7 ± 7.5 (stat) ± 3.6 (syst) μm

$\Delta\Gamma_s$ = 0.075 ± 0.035 (stat) ± 0.01 (syst) ps^{-1}

$|A_{||}(0)|^2$ = 0.231 ± 0.014 (stat) ± 0.015 (syst)

$|A_0(0)|^2$ = 0.524 ± 0.013 (stat) ± 0.015 (syst).

Prospects

- Possible analysis improvements:

  - Improve statistics by ~25-30% by adding $B_s \rightarrow J/\Psi\Phi$ decays from displaced track trigger (difficult due to trigger effects on decay time)

  - Addition of new decay modes:
    $B_s \rightarrow J/\Psi f^0$, *with* $f^0 \rightarrow \pi\pi$ (less statistics but no angular analysis needed since final state is *CP* eigen-state)
    $B_s \rightarrow \psi(2s)\Phi$

  - Perform KK mass dependent fit (for more precise determination of s-wave contamination)

- Add more data !

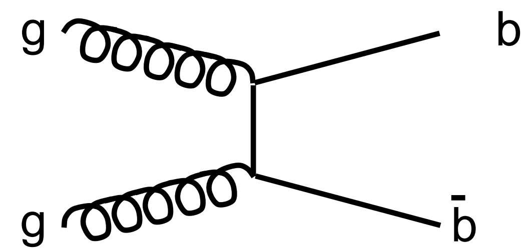
  - 7 fb^{-1} already recorded

  - expect to double sample size (~10 fb^{-1}) by end of Tevatron running in 2011

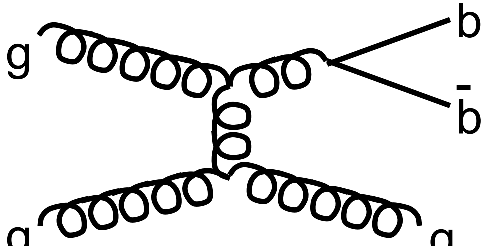
Backup Slides

B Physics at the Tevatron

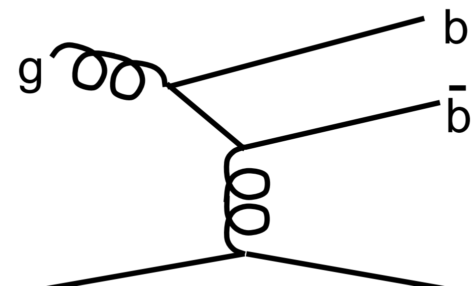
- Mechanisms for b production in $p\bar{p}$ collisions at 1.96 TeV



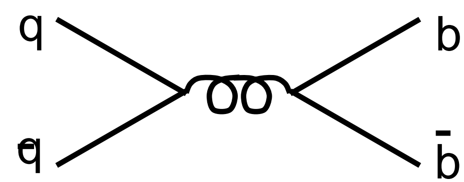
Flavor Creation (gluon fusion)



Gluon Splitting



Flavor Excitation



Flavor Creation (annihilation)

- At Tevatron, b production cross section is much larger compared to B-factories
  → Tevatron experiments CDF and DØ enjoy rich B Physics program

- Plethora of states accessible only at Tevatron: B_s, B_c, Λ_b, Ξ_b, Σ_b…
  → complement the B factories physics program

- Total inelastic cross section at Tevatron is ~1000 larger than b cross section
  → large backgrounds suppressed by triggers that target specific decays

β_s vs ϕ_s

- Up to now, introduced two different phases:

$$\phi_s^{SM} = \arg\left(-\frac{M_{12}}{\Gamma_{12}}\right) \approx 4x10^{-3}$$ and $$\beta_s^{\rm SM} = \arg(-V_{ts}V_{tb}^*/V_{cs}V_{cb}^*) \approx 0.02$$

- New Physics affects both phases by same quantity $\phi_s^{\rm NP}$ (arxiv:0705.3802v2):

$$2\beta_s = 2\beta_s^{\rm SM} - \phi_s^{\rm NP}$$

$$\phi_s = \phi_s^{\rm SM} + \phi_s^{\rm NP}$$

- If the new physics phase $\phi_s^{\rm NP}$ dominates over the SM phases $2\beta_s^{\rm SM}$ and $\phi_s^{\rm SM}$
→ neglect SM phases and obtain:

$$2\beta_s = -\phi_s^{\rm NP} = -\phi_s$$

Decay Rate

- $B_s \rightarrow J/\Psi\Phi$ decay rate (A.S. Dighe *et al.*, Phys. Lett. B **369** 144 (1996)) :

$$P_B(\theta,\phi,\psi,t) = \frac{9}{16\pi}|\mathbf{A}(t) \times \hat{n}|^2$$

where: $\mathbf{A}(t) = (\mathcal{A}_0(t)\cos\psi, -\frac{\mathcal{A}_\parallel(t)\sin\psi}{\sqrt{2}}, i\frac{\mathcal{A}_\perp(t)\sin\psi}{\sqrt{2}})$ and $\hat{n} = (\sin\theta\cos\phi, \sin\theta\sin\phi, \cos\theta)$

- Time evolution of transversity amplitudes A_0, $A_{||}$, $A_\perp$:

$$\mathcal{A}_i = \frac{e^{-\Gamma t/2}}{\sqrt{\tau_H + \tau_L \pm \cos 2\beta_s\,(\tau_L - \tau_H)}}\left[E_+(t) \pm e^{2i\beta_s}E_-(t)\right]a_i$$

where ± corresponds to CP-even and CP-odd final states, $\sum_i |a_i|^2 = 1$ and

$$E_\pm(t) \equiv \frac{1}{2}\left[e^{+\left(\frac{-\Delta\Gamma}{4}+i\frac{\Delta m}{2}\right)t} \pm e^{-\left(\frac{-\Delta\Gamma}{4}+i\frac{\Delta m}{2}\right)t}\right]$$

- Finally:

$$\begin{aligned} P_B(\theta,\psi,\phi,t) &= \frac{9}{16\pi}\left\{|\mathbf{A_+(t)} \times \hat{n}|^2 + |\mathbf{A_-(t)} \times \hat{n}|^2 + 2Re((\mathbf{A_+(t)} \times \hat{n}) \cdot (\mathbf{A^*_-(t)} \times \hat{n}))\right\} \\ &= \frac{9}{16\pi}\left\{|\mathbf{A}_+ \times \hat{n}|^2|f_+(t)|^2 + |\mathbf{A}_- \times \hat{n}|^2|f_-(t)|^2 + 2Re((\mathbf{A}_+ \times \hat{n}) \cdot (\mathbf{A}^*_- \times \hat{n}) \cdot f_+(t) \cdot f^*_-(t))\right\} \end{aligned}$$

$$|f_\pm(t)|^2 = \frac{1}{2}\frac{(1 \pm \cos 2\beta_s)e^{-\Gamma_L t} + (1 \mp \cos 2\beta_s)e^{-\Gamma_H t} \mp 2\sin 2\beta_s e^{-\Gamma t}\sin\Delta m t}{\tau_L(1 \pm \cos 2\beta_s) + \tau_H(1 \mp \cos 2\beta_s)}$$

$$f_+(t)f^*_-(t) = \frac{e^{-\Gamma t}\cos\Delta m t + i\cos 2\beta_s e^{-\Gamma t}\sin\Delta m t + i\sin 2\beta_s(e^{-\Gamma_L t} - e^{-\Gamma_H t})/2}{\sqrt{[(\tau_L - \tau_H)\sin 2\beta_s]^2 + 4\tau_L\tau_H}}$$

Decay Rate with S-Wave Included

- Including the s-wave contribution the probability density function becomes:

CP-odd

$$\rho_B(\theta,\phi,\psi,t,\mu) = \frac{9}{16\pi}\left|\left[\sqrt{1-F_s}\,g(\mu)\mathbf{A}(t) + e^{i\delta_s}\sqrt{F_s}\frac{h(\mu)}{\sqrt{3}}\mathbf{B}(t)\right]\times\hat{n}\right|^2$$

where: $\mathbf{B}(t) = (\mathcal{B}(t),0,0)$ and $\mathcal{B}(t) = \frac{e^{-\Gamma t/2}}{\sqrt{\tau_H+\tau_L-\cos 2\beta_s(\tau_L-\tau_H)}}\left[E_+(t) - e^{2i\beta_s}E_-(t)\right]$

g(μ) is relativistic Breit-Wigner to describe asymmetric *Φ* mass shape and *h(μ)* is constant

- Integrating out the dependence on the KK mass:

$$\begin{aligned}\rho_B(\theta,\psi,\phi,t) &= (1-F_s)\cdot P_B(\theta,\psi,\phi,t) + F_s Q_B(\theta,\psi,\phi,t)\\ &+ 2\frac{\sqrt{27}}{16\pi}Re\left[\mathcal{I}_\mu\left(((\mathbf{A}_-\times\hat{n})\cdot(\mathbf{B}\times\hat{n})\cdot|f_-(t)|^2 + (\mathbf{A}_+\times\hat{n})\cdot(\mathbf{B}\times\hat{n})\cdot f_+(t)\cdot f_-^*(t)\right)\right]\end{aligned}$$

where: $I(\mu)$ is a function of the s-wave phase and $Q_B(\theta,\phi,\psi,t) = \frac{3}{16\pi}|\mathbf{B}(t)\times\hat{n}|^2$

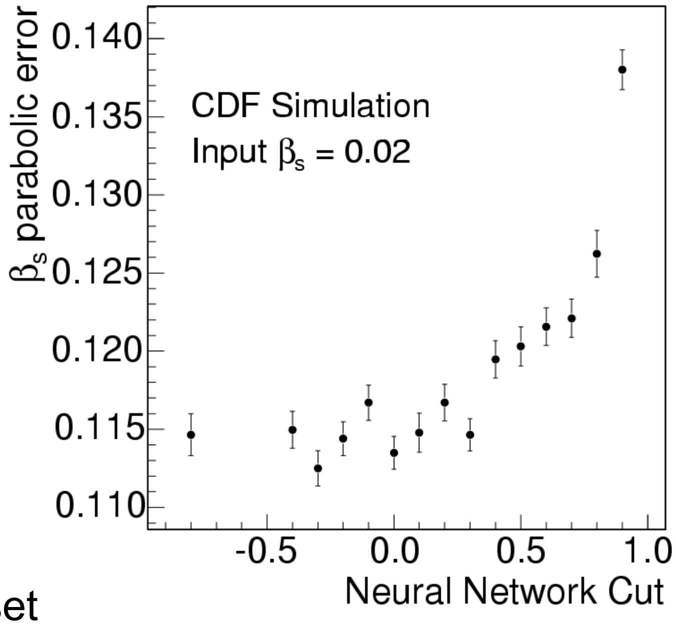
Analysis Improvements with Respect To 2008 Update

- Almost doubled data sample (from 2.8 fb^{-1} in 2008 to 5.2 fb^{-1} now)

- Improved signal selection:

  - use particle ID (dE/dx and TOF) for full dataset

  - use pseudo-experiments to optimize neural network selection to minimize β_s statistical uncertainty (previously used $S/(S+B)^{1/2}$ as figure of merit)



- Same side kaon tagger (SSKT) used for the full dataset

  - re-calibrated by measuring B_s mixing frequency with 5.2 fb^{-1}

- Inclusion of S-wave contamination in the likelihood fit

S-Wave Cross Check Using KK Mass Spectrum

- Cross check the result from angular fit by fitting the KK invariant mass spectrum

- From a fit to the B_s mass distribution with wide KK mass range selection (0.980,1.080 GeV), determine contributions of combinatorial background, mis-reconstructed B^0, and B_s events

- Good fit of the KK mass spectrum with 2% f^0 contributions
